EXECUTIVE SUMMARY

At the request of NTSB, JMS has performed intact stability calculations for the passenger vessel ETHAN ALLEN. ETHAN ALLEN is a Dyer 40 fiberglass mono-hull design built in 1964 by the Anchorage in Warren, Rhode Island. The Dyer 40 has been in production since 1960 in a variety of configurations including launches similar to the ETHAN ALLEN.

On October 2, 2005 the NY state certified vessel Ethan Allen was touring Lake George with 47 passengers and one NY State licensed crewmember on board. The vessel proceeded northbound and approached an area on the lake called Cramer Point when the master began a turn to starboard. According to most of the passengers, the vessel heeled to port and capsized. After remaining inverted on the surface for a short period, the vessel subsequently sank. The master and 27 passengers survived. Twenty passengers died.

The ETHAN ALLEN was initially certificated by USCG to carry 48 passengers as a USCG 46 CFR Subchapter T vessel (Reference 1). During her 41 years of operation, the ETHAN ALLEN was modified several times with protective canopies over the passenger area. At the time of the accident a wooden canopy with retractable Plexiglas side windows covered the passenger area. The vessel had also been repowered with a single 110 horsepower diesel engine.

This report summarizes the findings of the first five tasks of NTSB's Statement of Work. These tasks are as follows:

1. Develop an accurate computer model of the vessel hull form
2. Calculate the lightship weight and center of ETHAN ALLEN, at the time of the accident, based on the inclining experiment conducted on sister vessel deCHAMPLAIN (Reference 2).
3. Calculate the lightship weight and center of ETHAN ALLEN for several previous conditions of the vessel: as delivered by the builder, and with multiple designs of canvas canopy.
4. Based on the lightship weights and centers found in Tasks 2 and 3, determine the maximum passenger loading that will meet USCG simplified stability criteria in 46 CFR 178.330 (Reference 3).
5. Based on the lightship weights and centers found in Tasks 2 and 3, determine the maximum passenger loading that will meet USCG stability criteria in 46 CFR Subchapter S: 46 CFR 170.170 Wind Heeling Moment (Reference 4), 46 CFR 170.173 Vessels of Unusual Form (Reference 5), 46 CFR 171.050 Passenger Heeling Moment (Reference 6).

In order to develop the hull form for the vessel, a laser survey was completed by 3D Measure Inc. of Newport, Rhode Island. This survey yielded a three dimensional computer model that could be imported into HECSALV stability software for the analysis.

The lightship weight and longitudinal center of gravity of ETHAN ALLEN at the time of the accident was estimated based on the weight measured on a truck scale, along with freeboard measurements of the vessel afloat (Reference 7). The vertical center was calculated based on the inclining test performed on the sister vessel, deCHAMPLAIN, (Reference 2). The hydrostatic properties based on Task 1 were used for both vessels. The resulting weight and center are given in Table 1.

Table 1. ETHAN ALLEN 2005 Lightship Condition

Lightship Weight	14,689 lbs
VCG	5.29 feet above BL
LCG	19.5 feet aft FP

Figure 1 shows a flow chart of the various vessel configurations and calculations in Tasks 3 through 5. These include multiple canopy designs as well as calculations in salt and fresh water. This represents the vessel's previous operation on the Thames River, Connecticut and recent operation on Lake George. For the simplified stability test, a center of gravity of the test weights is specified as 2.5 feet above the deck. At the request of NTSB, a center of gravity of 1.5 feet above the deck is also examined for the as delivered case.

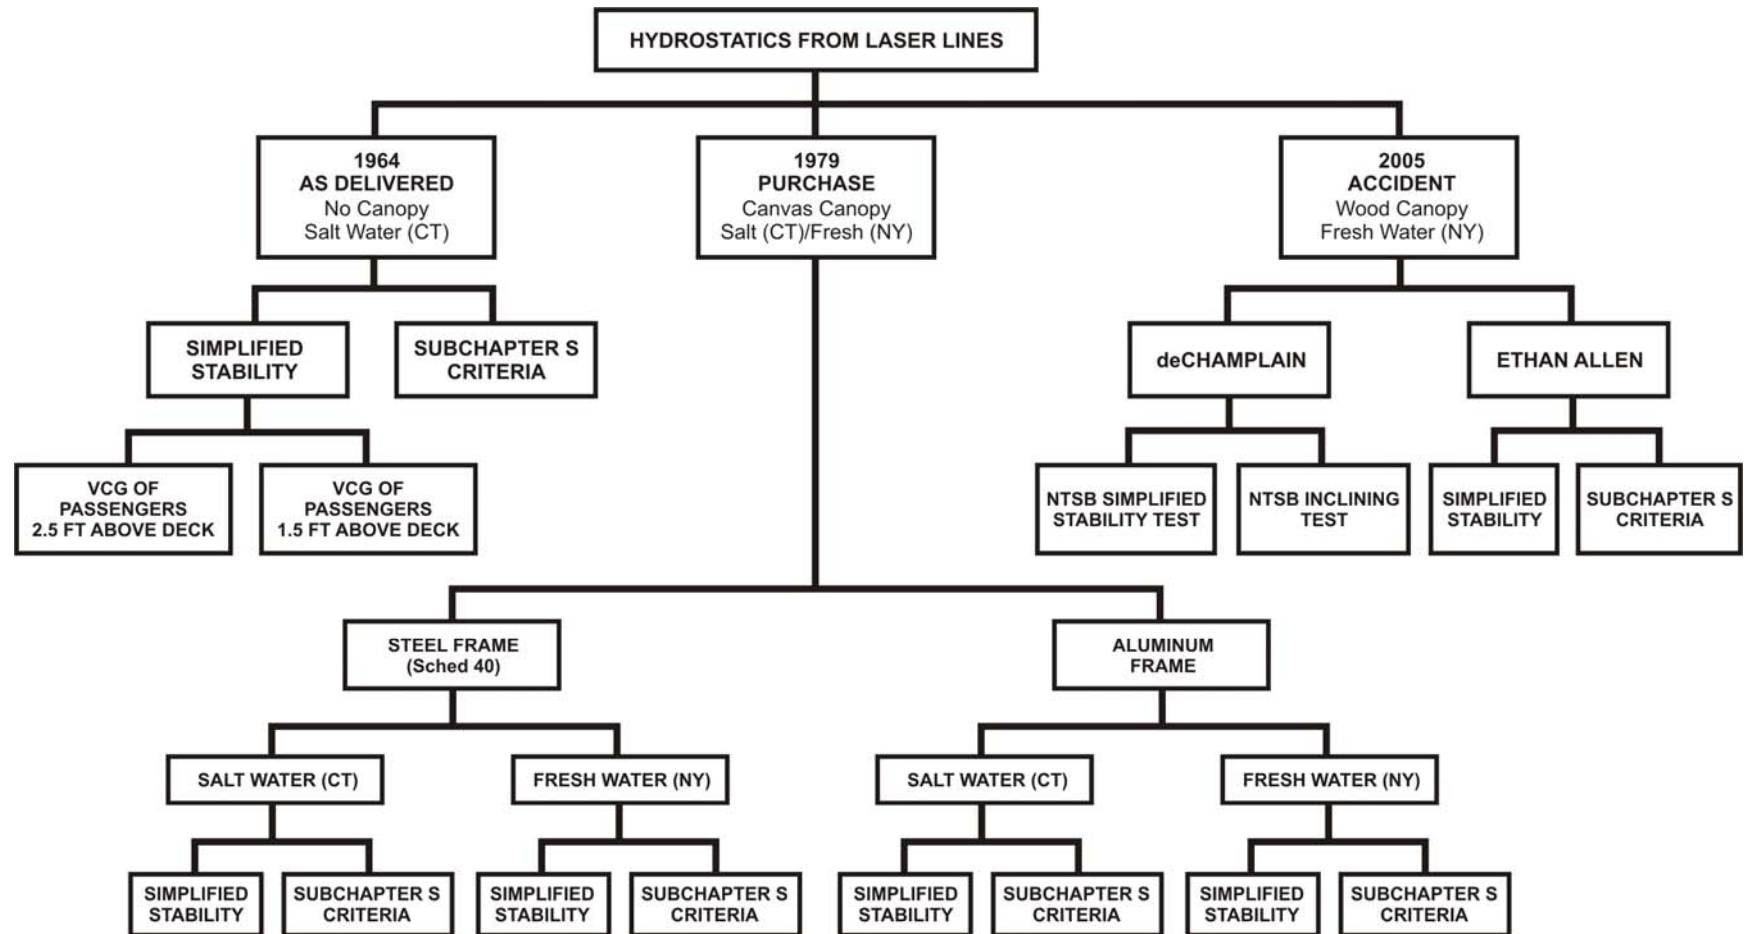

Figure 1. Flow Chart of Stability Calculations

Scarano Boatbuilding's report, Reference 8, presents several canopy designs. Three of these are considered in this analysis – canvas canopy with schedule 40 steel frame, canvas canopy with schedule 40 aluminum frame, and final wooden canopy. The vessel reportedly had no canopy when originally delivered. Lightship weights and centers of the five vessel configurations are shown in Table 2. deCHAMPLAIN is included as a benchmark, using the results of the inclining experiment,. Reference 2.

Table 2. Lightship Conditions of Alternate Vessel Configurations

	1964	Steel Canopy	Al Canopy	deCHAMPLAIN	2005
Weight	12,759 lbs	14,590 lbs	13,542 lbs	14,315 lbs	14,689 lbs
VCG	4.5 feet abv BL	5.4 feet abv BL	4.9 feet abv BL	5.4 feet abv BL	5.3 feet abv BL
LCG	19.4 feet aft FP	19.5 feet aft FP	19.4 feet aft FP	19.8 feet aft FP	19.5 feet aft FP

Only the vessel design with no canopy can pass the simplified stability test, regardless of the number of passengers. This is because with the canopy installed, the wind heeling moment is governing over the passenger heeling moment. The marginal stability was also borne out in the test that was performed on the deCHAMPLAIN by NTSB on 5 October 2005. (Reference 9). During that test, approximately half of the required heeling moment was imposed before the test was halted when the vessel was close to the minimum freeboard. Table 3 shows the results of Task 4 – maximum passenger loading for simplified stability criterion. Passenger counts are based on 140 pounds per person, the USCG standard for protected waters.

Table 3. Maximum Passenger Loading for Simplified Stability Test

Condition	Total Passenger Weight	Passengers (140 lb/pax)
1964 – VCG 2.5 ft abv deck	5,740 lb	41
1964 – VCG 1.5 ft abv deck	6,580 lb	47

Table 4 shows the results of Task 5 – maximum passenger loading for Subchapter S criteria. Passenger counts are based on 140 pounds per person, the USCG standard for protected waters. As in the simplified criteria, canopy conditions do not meet the wind heel criteria regardless of passenger count. The wood canopy does meet the criteria with a reduced number of passengers. This is because the wood canopy is lower than the canvas.

Table 4. Maximum Passenger Loading for Subchapter S Stability Criteria

Condition	170.170 Wind Heel		170.173 Unusual Form		171.050 Passenger Heel	
	Total Passenger Weight	Passengers (140 lb/pax)	Total Passenger Weight	Passengers (140 lb/pax)	Total Passenger Weight	Passengers (140 lb/pax)
1964 – as delivered	>21,000	>150	8,260	59	8,120	58

VESSEL PARTICULARS

Owner: Shoreline Cruises, Lake George, NY
 Built: 1964 – The Anchorage, Warren, RI
 Model: Dyer 40
 Hull No.: 7

Length Overall:	39.5	ft
Length Between Perpendiculars	33.5	ft
Beam:	12.4	ft (molded, MS)
Depth:	5.93	ft (molded, MS)

TASK 1

3D Measure Incorporated was contracted by JMS Naval Architects to measure and produce an as-built offset file of the ETHAN ALLEN.

The following persons were present during the measurement: Robert W. Henry, Naval Architect, and Barry Strauch, Ph.D. from the National Transportation Safety Board, Washington, DC, T. Blake Powell, and Rick Fernandes from JMS Naval Architects & Salvage Engineers, Groton, CT.

The measurement was done on the ETHAN ALLEN on February 16, 2006 in Lake George, New York. The vessel was firmly supported by jack stands and wooden blocks under the keel.

Laser measurement points were taken using a Nikon NPL 820 Digital Pulse Laser Total Station. The instrument was checked for accuracy several times during the measurement and the accuracy was found to be within 2mm. Data points were collected on the port side, starboard side, bow and transom of the vessel. A total of 645 data points were collected. Measured points were then imported from the Nikon Total Station onto a laptop using Nikon Transit software version 2.31. Points were then imported into MultiSurf, a Computer Added Design (CAD) software program. Collected data points were reviewed by representatives of NTSB and JMS.

The data was used to produce a wire frame and a surface model. The surfaces were then checked against the original data points. Most of the points were less than 1.5mm from the surface. The surface model was vertically sliced into 46 stations defining the hull for the HECSALV hydrostatic program. Figure 2 shows the surface hull model in Rhinoceros. Figure 3 shows the wire frame station model in HECSALV.

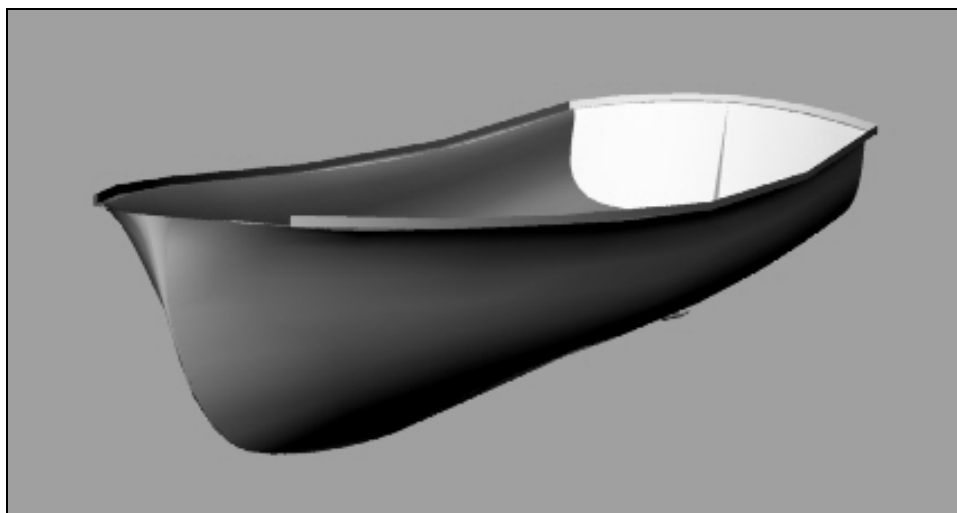

Figure 2. 3D Model of Ethan Allen Hull

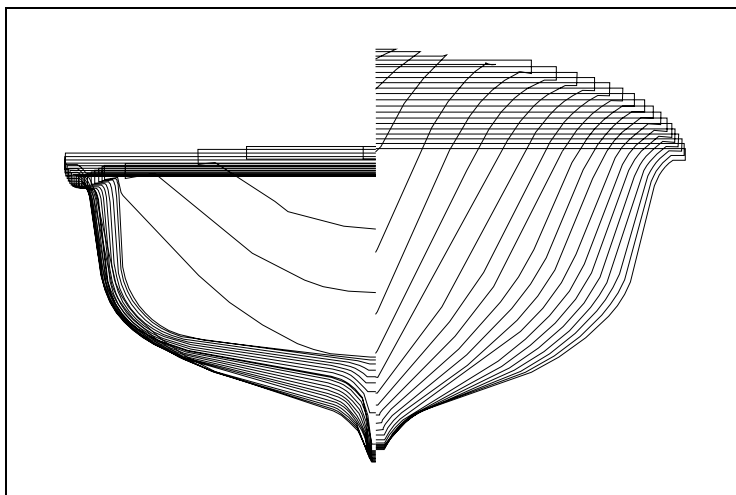

Figure 3. Hydrostatic Model of Ethan Allen Hull

Assumptions

Several key assumptions affect interpretation of the hull model and analysis.

1. The baseline of the vessel is assumed to be at the bottom of the vessel at midships. This differs from the previous model and lines plans, which had the baseline 6.5 inches below the bottom of the vessel.
2. The length between perpendiculars is measured from the rudder stock to the intersection of the stem with the 2.47 foot reference waterline.
3. Passenger weight distribution is based on a uniform weight of passengers seated in the 2005 bench arrangement. This is slightly asymmetrical due to the arrangement of three-seater benches on the port side and two-seaters on the starboard side (Reference 10).
4. Offsets were measured to the outside of the hull. Therefore, there is no allowance for the sidsheer. Because the displacement of the rudder and propeller are small, they are ignored in this analysis.

Description of Computer Model

A computer model of the vessel was created using Herbert Engineering Corporation's hydrostatic software package, HECSALV Version 7.6.6. This model includes hull offsets and hydrostatic properties, compartments and subdivision, and weights and centers. All information necessary for intact or damaged stability calculations is present.

Two models were used for this analysis. The first abbreviated model contained only the minimum required, allowing the displacement to be calculated from freeboard measurements. For the stability calculations, the model is constructed including compartments, weights, and centers, based on the 1964 vessel as delivered. For the alternative configurations, the canopy is included as a deadweight item.

Details of the HECSALV model are contained in Appendix A.

TASK 2

Overview

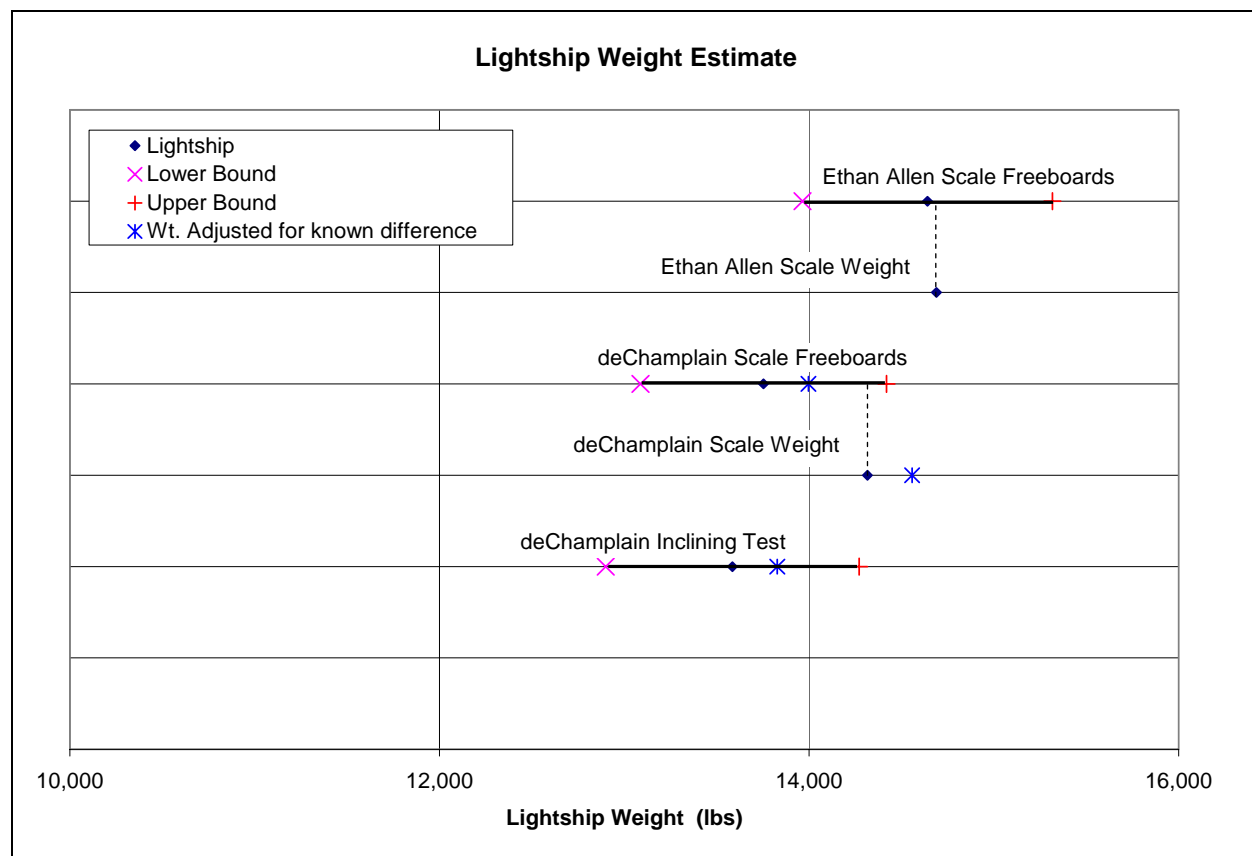

The lightship weight and center of gravity of the ETHAN ALLEN were calculated based on results of several tests conducted by NTSB on this vessel and sister vessel deCHAMPLAIN. These include weight of both vessels measured on NY State Police truck scale and freeboards taken at the same time (Reference 7), and inclining test on deCHAMPLAIN (Reference 2). The results of all tests were calculated using the hydrostatic model developed from the laser measurement. Detailed calculations are included in Appendix B.

Table 5 and Figure 4 show the results for all five lightship estimates. The accuracy of the NY State Police scale is 2 percent, per NTSB, and the total weight – including truck and trailer – was 33,000 lbs for each test. Two percent corresponds to plus or minus approximately 660 pounds. In the draft range of these measurements, parallel sinkage of the vessel is approximately 1,300 pounds per inch. Therefore, one half inch of freeboard is equivalent to plus or minus 650 pounds. There is approximately 250 pounds of known weight difference between deCHAMPLAIN and ETHAN ALLEN: 150 lbs canopy, 38 lbs engine, and 55 lbs ballast; in all cases, ETHAN ALLEN is the heavier vessel.

The calculated weights at the time of each test were adjusted for deadweight items that were on board the vessels. Both vessels had some fuel on board. In addition, ETHAN ALLEN had water in the bilges and various gear. There were a hatch cover and one window missing from the ETHAN ALLEN at the time of the test. In the case of the deCHAMPLAIN inclining test, the deadweight adjustment includes personnel and test equipment.

Table 5. Lightship Weight Estimate

Vessel	Source	Date	Weight (pounds)	Deadweight (pounds)	Lightship (pounds)	LS Draft (in @ LCF)
Ethan Allen	Freeboards	12-Oct	15,252	611	14,641	29.26
Ethan Allen	Scale	12-Oct	15,300	611	14,689	29.29
deChamplain	Freeboards	12-Oct	14,288	535	13,753	28.61
deChamplain	Scale	12-Oct	14,850	535	14,315	29.03
deChamplain	Inclining	5-Oct	15,857	2,272	13,585	28.47

Because there is good agreement between the five weight estimates, the truck scale weight for the ETHAN ALLEN is used as the base weight in the stability calculations. The center of gravity was calculated from other data. The longitudinal center was derived from the freeboard measurements taken at the time of the scale test. The vertical center was adjusted from the deCHAMPLAIN inclining test.

**Table 6. Lightship Weight and Centers
ETHAN ALLEN 2005**

Weight	14,689 lb
VCG	5.3 ft aBL
LCG	19.5 ft aFP
Draft @ LCF	2.44 ft

Calculations

Freeboard measurements were taken at five positions along the hull for all of the tests. These five positions were in approximately the same location each time: bow, transom, and three intermediate points. Using the surveyed shear line and the measured freeboards, drafts were calculated for each test. Figure 4 shows an example of drafts over the length of the vessel. This plot is for the ETHAN ALLEN. Similar plots were constructed for the deCHAMPLAIN tests.

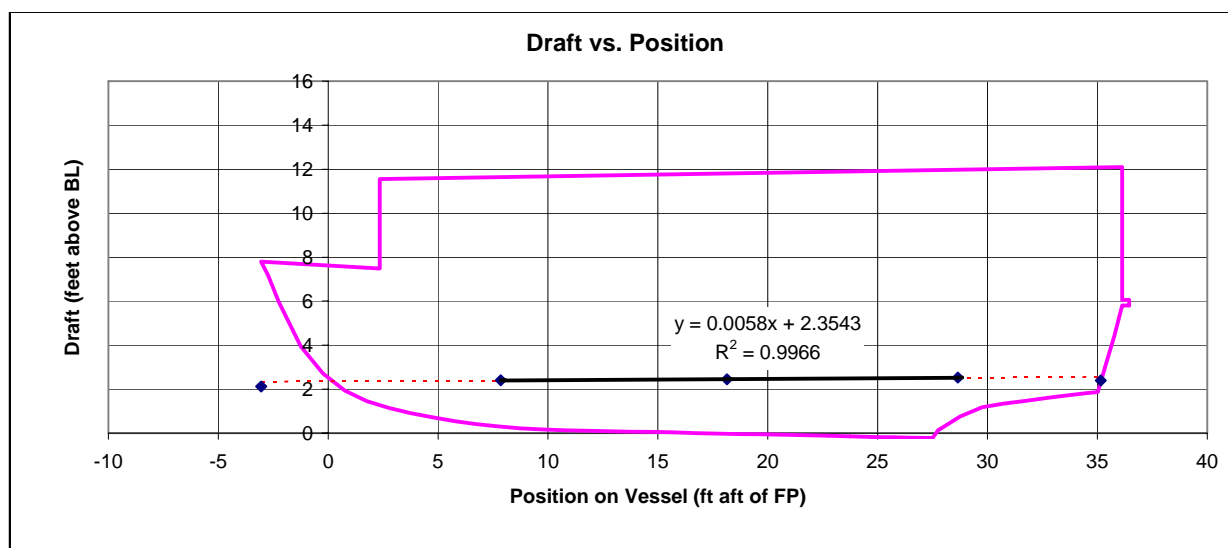

Figure 4. ETHAN ALLEN Drafts at Time of Truck Scale Weight Test

A straight line was fit through the center three points. This yields very good agreement (within 0.05 inches) with the center three points and agreement within 2.5 inches at the ends. This same process was used for the deCHAMPLAIN tests.

The weight and center derived from truck scale freeboards were adjusted for deadweight items that were on board the vessel at the time of the test, as shown in Table 7.

Table 7. Weights and LCG – Truck Scale Survey

	Weight	LCG
Test Weight	15,300 lb	19.3 ft aFP
Fuel	-178 lb	12.5 ft aFP
Water	-383 lb	14.6 ft aFP
Gear	-100 lb	13.0 ft aFP
To be added	50 lb	5.5 ft aFP
Lightship	14,689 lb	19.5 ft aFP

In order to determine the vertical center of gravity (VCG) of ETHAN ALLEN, data from the deCHAMPLAIN inclining test must be used. The known weight differences between ETHAN ALLEN and deCHAMPLAIN are in the engines, fixed ballast, and canopy; see Table 8. (Engine weights are taken from Reference 11.) Fixed ballast weights are based on the condition of the vessels at the time of survey as well as confirmation of unit weight of lead blocks (Reference 12). By adjusting for these known differences, the VCG of the hull portion of deCHAMPLAIN was calculated. Although the hull weight for deCHAMPLAIN and ETHAN ALLEN may not be exactly the same, due to minor construction or outfitting differences, it is assumed that the weight difference is evenly distributed over the hull and therefore the same VCG can be used for both vessels. The total lightweight VCG for ETHAN ALLEN is then built up by adding back the ballast, engine, and canopy, see Table 9.

Table 8. Weights and VCG – deCHAMPLAIN

	Weight	VCG
Lightship	13,585 lb	5.25 ft aBL
Engine	1,082 lb	3.00 ft aBL
Ballast	1,210 lb	1.75 ft aBL
Canopy	1,780 lb	10.8 ft aBL
Hull	9,513 lb	4.91 ft aBL

Table 9. Weights and VCG – ETHAN ALLEN

	Weight	VCG
Hull	10,484 lb	4.91 ft aBL
Engine	1,120 lb	3.00 ft aBL
Ballast	1,155 lb	1.75 ft aBL
Canopy	1,930 lb	10.8 ft aBL
Lightship	14,689 lb	5.29 ft aBL

TASK 3

The evaluation of multiple canopy variations is based on weight estimates from Scarano in Reference 8. Four different conditions were considered:

1. 1964 As Delivered, No canopy
2. 1979 Canvas canopy with schedule 40 steel frame (1831 lb)
3. 1979 Canvas canopy with schedule 40 aluminum frame (783 lb)
4. 2005 Time of accident, Wood canopy (1930 lb)

Weights from Reference 8 were confirmed based on the following assumptions:

- Height of the canvas canopy is 7'-11.44" above the deck at boarding threshold. This is scaled from photographs. Height of the wood canopy is 6'-8.25" above the deck at the boarding threshold, per Reference 8. This is confirmed by measurements taken by JMS.

- Longitudinal center of all canopies is taken to be 23 feet aft of the bow. This is in consideration of slightly more area in plan view aft.
- All canopies have the same arrangement of plexiglass windows. Total weight of windows is approximately 145 pounds based on 3/16" plexiglass on the existing canopy. The same value is used for the canvas canopy arrangements.

Table 10 summarizes the vessel lightship weight and center adjusted for each canopy configuration.

Table 10. Lightship Characteristics – Canopy Variations

	1. 1964	2. 1979	3. 1979	4. 2005
Canopy	None	Steel Frame	Al Frame	Wood
Lightship Weight	12,759 lb	14,590 lb	13,542 lb	14,689 lb
VCG	4.5 ft aBL	5.4 ft aBL	4.9 ft aBL	5.3 ft aBL
LCG	19.4 ft aFP	19.5 ft aFP	19.4 ft aFP	19.5 ft aFP

TASK 4

The maximum passenger load that passes the simplified stability test was calculated for each of the conditions in Task 3. In addition, the 1979 canvas canopy conditions were analyzed in both fresh and salt water to evaluate stability in Thames River, Connecticut, where it originally operated. The simplified stability test specifies a center of hypothetical passenger weight to be located 2.5 feet above the passenger deck. For the 1964 condition only, a VCG of 1.5 feet above the deck was also considered. The 1964 condition is additionally analyzed using salt water. Because the minimum freeboard occurs further than 3/4 of the length from the bow, the reference point is taken at 3/4 of the length.

The number of 140 lb passengers (protected waters) was adjusted for each condition until the stability criteria were met. Detailed calculations are included in Appendix C.

Applicable Standards

46 CFR § 178.330 specifies the procedure and calculations for the simplified stability test.

(a) A vessel must be in the condition specified in this paragraph when a simplified stability proof test is performed.

(3) Each fuel and water tank must be approximately three-quarters full.

(4) A weight equal to the total weight of all passengers, crew, and other loads permitted on the vessel must be on board and distributed so as to provide normal operating trim and to simulate the vertical center of gravity causing the least stable condition that is likely to occur in service. Unless otherwise specified, weight and vertical center of gravity is assumed to be as follows:

(ii) The weight of one person is considered to be 72.6 kilograms (160 pounds) except the weight of one person is considered to be 63.5 kilograms (140 pounds) if the vessel operates exclusively on protected waters and the passenger load consists of men, women, and children;

(iii) The vertical center for the simulated weight of passengers, crew, and other loads must be at least 760 millimeters (2.5 feet) above the deck; and

(5) All non-return closures on cockpit scuppers or on weather deck drains must be kept open during the test.

(b) A vessel must not exceed the limitations in paragraph (f) of this section, when subjected to the greater of the following heeling moments:

$$M_p = (W) (B_p)/6; \text{ or}$$

$$M_w = (P) (A) (H)$$

where:

M_p = passenger heeling moment in kilogram-meters (foot-pounds);

W = the total passenger weight using 72.6 kilograms (160 pounds) per passenger, or, if the vessel operates exclusively on protected waters and the passenger load consists of men, women, and children, 63.5 kilograms (140 pounds) per passenger may be used;

B_p = the maximum transverse distance in meters (feet) of a deck that is accessible to passengers;

M_w = wind heeling moment in kilogram-meters (foot-pounds);

P = wind pressure of:

(1) 36.6 kilograms/square meter (7.5 pounds/square foot) for operation on protected waters;

(2) 48.8 kilogram/square meter (10.0 pounds/square foot) for operation on partially protected waters; or

(3) 73.3 kilograms/square meter (15.0 pounds/square foot) for operation on exposed waters;

A = area, in square meters (square feet), of the projected lateral surface of the vessel above the waterline (including each projected area of the hull, superstructure and area bounded by railings and structural canopies).

H = height, in meters (feet), of the center of area (A) above the waterline, measured up from the waterline.

(d) A vessel must not exceed the following limits of heel:

(1) On a flush deck vessel, not more than one-half of the freeboard may be immersed.

(6) In no case may the angle of heel exceed 14 degrees.

(e) The limits of heel must be measured at:

(1) The point of minimum freeboard; or

(2) At a point three-quarters of the vessel's length from the bow if the point of minimum freeboard is aft of this point.

(f) When demonstrating compliance with paragraph (d) of this section, the freeboard must be measured as follows:

(1) For a flush deck or well deck vessel, the freeboard must be measured to the top of the weatherdeck at the side of the vessel.

Results

Table 11 shows the maximum number of 140 lb passengers that may be carried in each lightship condition if the simplified stability criterion is to be met. Because of the wind heel requirement, only the cases with no canopy pass, regardless of the number of passengers.

Table 11. Maximum Passenger Loading for Simplified Stability Test

Condition	Total Passenger Weight	Passengers (140 lb/pax)
1964 – VCG 2.5 ft abv deck	5,740 lb	41
1964 – VCG 1.5 ft abv deck	6,580 lb	47

There are several factors that influence the simplified stability test. The heeling moment required for the test is the greater of passenger heel and wind heel. Where passenger heel is governing, heeling moment is independent of draft and directly proportional to the number of passengers. As passengers are removed, VCG is reduced, and righting moment is correspondingly increased. Figure 5 shows heeling and righting moments for the 1964 conditions. The righting moment is shown in the upright position with deadweight positioned on centerline.

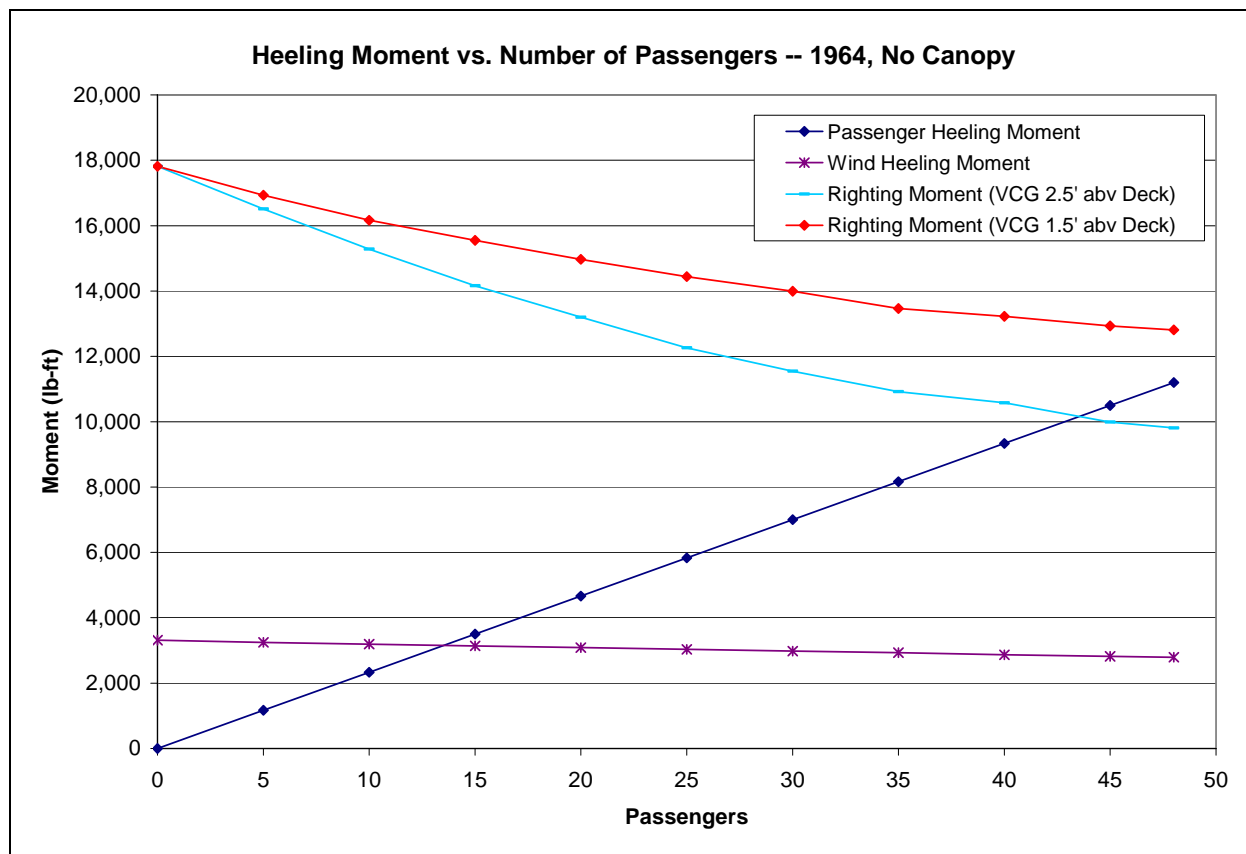

Figure 5. Heeling Moments – 1964, No Canopy

In cases where wind heel is governing, heeling moment is increased as passengers are removed. This does not correspond to increased passenger load being more stable, however, because as passengers are added the VCG increases, and the freeboard decreases reducing the allowable heel angle. Figure 6 compares heeling moments for the 2005 condition with wooden canopy.

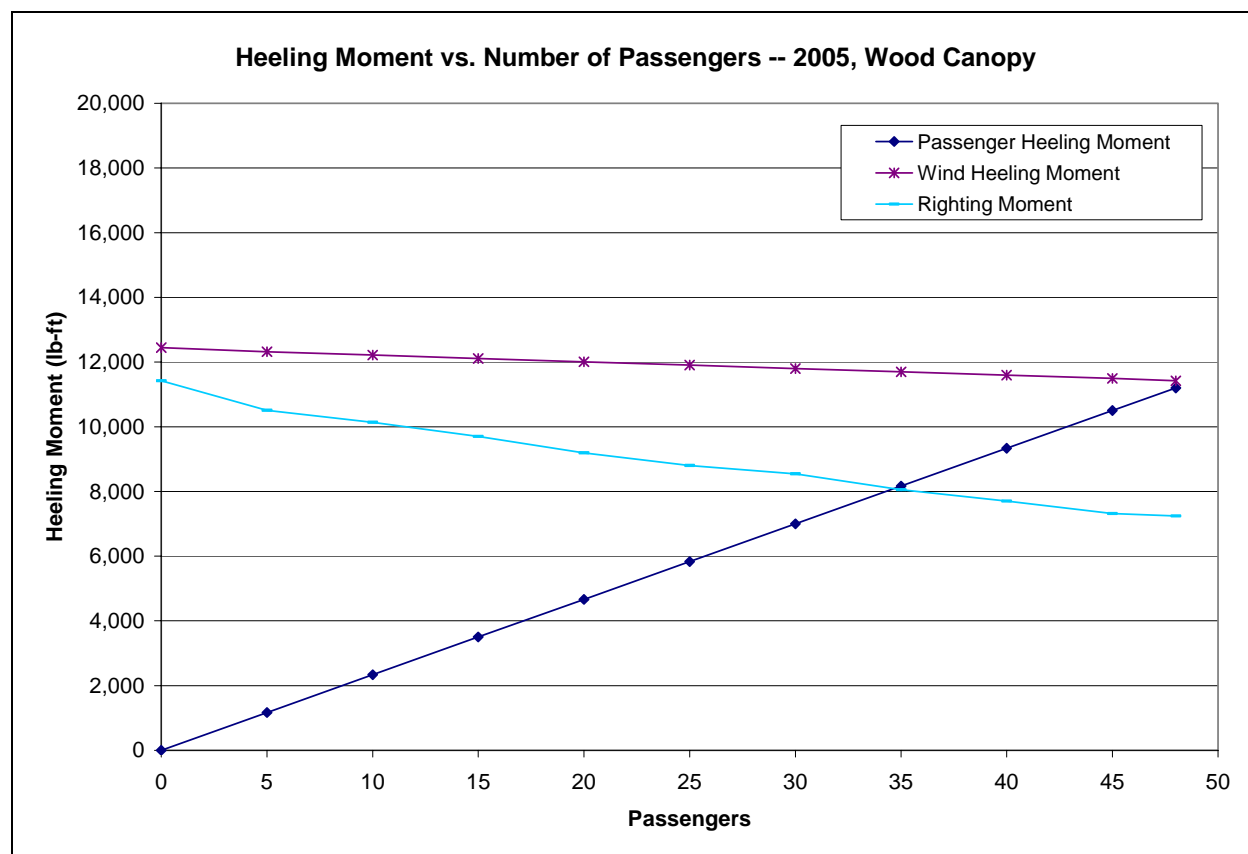

Figure 6. Heeling Moments – 2005, Wood Canopy

In all of the conditions with a canopy, the sail area must include everything below the top of the canopy whether windows are assumed to be open or closed. This results in a wind heeling moment so high that the righting moment is never sufficient to counter it.

TASK 5

The maximum passenger loading that will meet the USCG stability criteria found in 46 CFR Subchapter "S" was determined based on the vessel conditions calculated in Tasks 2 and 3. For the Subchapter S calculations, it is assumed that the center of gravity of the combined passengers is at the geometric center of the passenger benches. This is 20 inches above deck and slightly to port. It is further assumed that the 1964 vessel has no canopy. Canopy dimensions for the other arrangements are based on Reference 8.

Applicable Standards

The vessel is required to meet the applicable stability requirements specified under Subchapter T – Rules Pertaining to Small Passenger Vessels. It has been determined that the applicable requirements of Subchapter S – Subdivision and Stability the vessel is required to meet are 46 CFR § 170.170 (Weather Criteria), 46 CFR § 170.173 (Vessels of Unusual Form), and 46 CFR § 171.050 (Passenger Heel). For each standard, the stability criteria was calculated then converted to a maximum total passenger weight.

§170.170 (a) Weather Criteria

The vessel must be shown to have a GM greater than the following:

$$GM \geq \frac{PAH}{W \tan (T)}$$

Where: $P = 0.0025 + (L / 14200)^2$ tons/ft² for service on protected waters

- L = vessel length between perpendiculars
 A = projected lateral area in square feet of the portion of the vessel and deck above the waterline
 H = the vertical distance from the center of A to the center of the underwater lateral area.
 W = displacement
 T = the lesser of 14 degrees heel or the angle of heel at which one-half the freeboard to the deck edge is immersed.

§170.173 Vessels of unusual proportion and form

The vessel was evaluated based on the criterion for vessels of unusual proportion and form. This is a righting energy criterion that is applicable to mechanically powered vessels under 100 meters in length, per 46 CFR 170.170(d).

(e) For the purpose of demonstrating acceptable stability ... compliance with paragraphs (a) through (d) of this section or the following criteria is required:

- (2) For protected routes, there must be –
- (i) Positive righting arms to at least 25 degrees of heel;
 - (ii) No downflooding point to at least 15 degrees; and
 - (iii) At least 10 foot-degrees of energy to the smallest of the following angles:
 - (A) The angle of maximum righting arm.
 - (B) The downflooding angle.
 - (C) 40 degrees.

§171.050 Passenger heel

The vessel must be shown to have a GM greater than the following:

$$GM \geq \frac{Nb}{(K)(W) \tan (T)}$$

where –

N = number of passengers

W = displacement of the vessel in long tons

T = 14 degrees or the angle of heel at which the deck edge is first submerged, whichever is less.

b = distance in feet from the centerline of the vessel to the geometric center of the passenger deck on one side of the centerline

K = 24 passengers/long ton

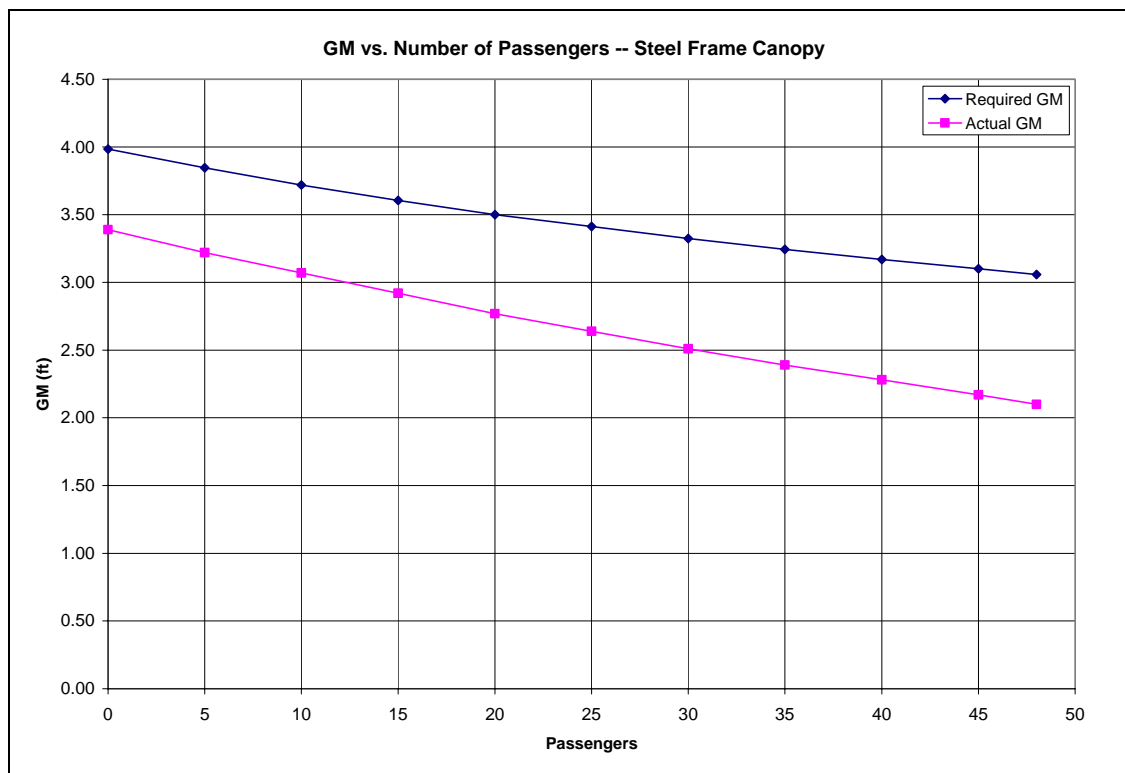

Results

Table 12 shows the results of Task 5 – maximum passenger loading for Subchapter S criteria. Passenger counts are based on 140 pounds per person, the USCG standard for protected waters. As in the simplified criteria, canopy conditions do not meet the wind heel criteria regardless of passenger count. The wood canopy does meet the criteria with a reduced number of passengers. This is because the wood canopy is lower than the canvas.

Figures 7, 8 and 9 show required and actual GM for the steel, aluminum and wood canopies, based on 170.170 wind heel criteria. These graphs show that for steel and aluminum canopies, the vessel cannot meet the criteria regardless of passenger loading. The wood canopy graph is included to illustrate what the curves look like in an arrangement that meets the criteria.

Table 12. Maximum Passenger Loading for Subchapter S Stability Criteria

Condition	170.170 Wind Heel		170.173 Unusual Form		171.050 Passenger Heel	
	Total Passenger Weight	Passengers (140 lb/pax)	Total Passenger Weight	Passengers (140 lb/pax)	Total Passenger Weight	Passengers (140 lb/pax)
1964 – as delivered	>21,000	>150	8,260	59	8,120	58
1979 – Steel Canopy – SW	FAIL		1,540	11	6,860	49

**Figure 7. GM vs. Passengers – Steel Canopy**

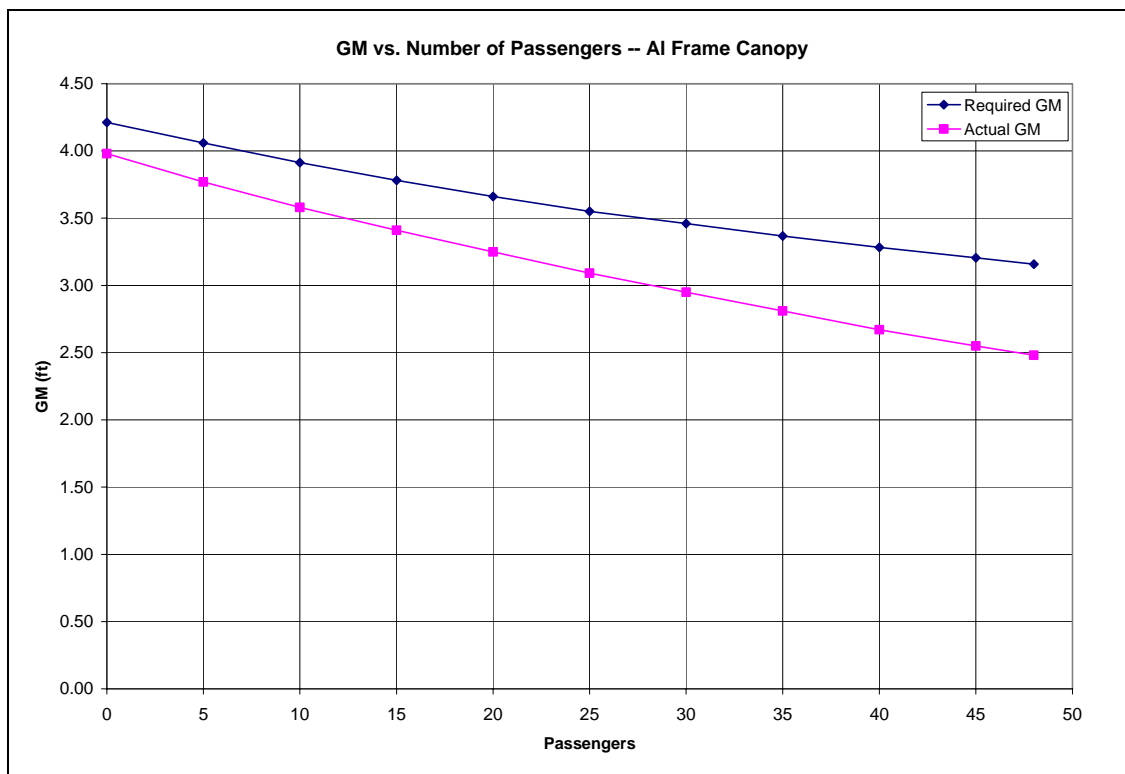

Figure 8. GM vs. Passengers – Aluminum Canopy

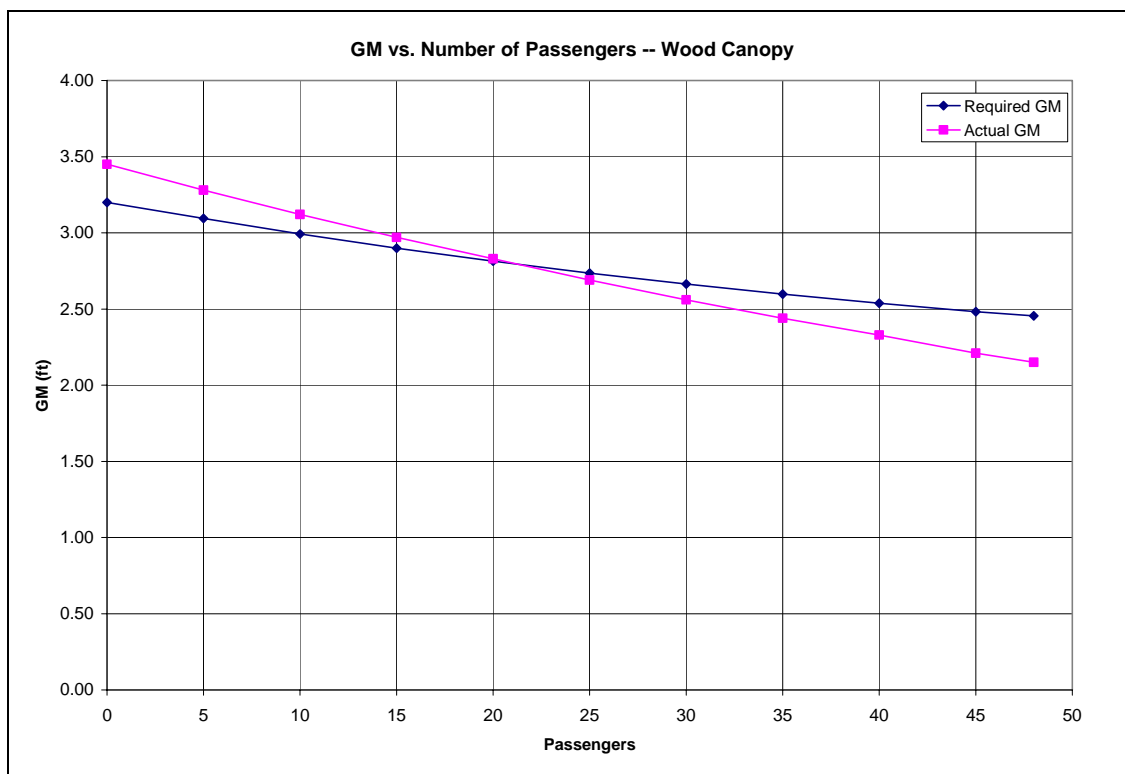

Figure 9. GM vs. Passengers – Wood Canopy

Because of the heavier weight and higher center of gravity, the steel and wood canopy configurations require a substantially reduced passenger load to pass the unusual form criteria. The governing criterion is the righting energy of 10 ft-deg up to the maximum GZ. The GZ curve of these arrangements is relatively flat, and the righting energy with 48 passengers is approximately 5 ft-deg.

All of the conditions pass the passenger heeling moment criterion. The maximum number of passengers that can be carried is calculated as only somewhat higher than the 48 certified. The highest being 58 passengers in the 1964 condition.

INTACT STABILITY CALCULATIONS

ETHAN ALLEN INVESTIGATION DELIVERABLE 1: TASKS 1 - 5

SIMPLIFIED STABILITY TEST

ETHAN ALLEN**Stability Analysis****46 CFR - PART 178 - INTACT STABILITY AND SEAWORTHINESS****SUBPART C - Intact Stability Standards****§178.330 - Simplified stability proof test**

Assumptions for are conditions:

Fuel tanks are 75% full. (75 gal, 535 lb.)

Minimum freeboard occurs at passenger threshold:

9.74' aft MS

5.98' off CL

5.47' aBL

Weight of passengers is 140# ea. for operation in protected waters.

Stability Analysis

46 CFR - PART 178 - INTACT STABILITY AND SEAWORTHINESS

SUBPART C - Intact Stability Standards

§178.330 - Simplified stability proof test

Assumptions for all conditions:

Fuel tanks are 75% full. (75 gal, 535 lb.)

Minimum freeboard occurs at passenger threshold:

9.74' aft MS

5.98' off CL

5.47' aBL

Weight of passengers is 140# ea. for operation in protected waters.

(1) Total Test Weight Required		1964-SW-2.5	1964-SW-1.5	1979-Steel-SW	1979-Steel-FW	1979-AI-SW	1979-AI-FW	2005-FW
No. of Passengers		41	47	28	27	27	27	22
Weight/Passenger	lb/pass.	140	140	140	140	140	140	140
Total Test Weight	lb	5740	6580	3920	3780	3780	3780	3080

(2) Distribution of Test Weight

<<Not Applicable. Main deck only.>>

46 CFR - PART 170 - STABILITY REQUIREMENTS FOR ALL INSPECTED VESSELS

SUBPART E - Weather Criteria -

§170.173 - Criterion for vessels of unusual proportion and form

(e)(2) For protected routes, there must be --

(i) The righting arm curve must be positive to at least 25 degrees of heel;

(ii) No downflooding point to at least 15 degrees; and

(iii) at least 10 foot-degrees of energy to the smallest of the following angles:

(A) Angle of maximum righting arm

(B) Angle of downflooding

(C) 40 degrees

Stability Analysis

46 CFR - PART 171 - SPECIAL RULES PERTAINING TO VESSELS CARRYING PASSENGERS

SUBPART C - Large Vessels

§171.050 - Intact stability requirements for a mechanically propelled or a nonself-propelled vessel.

$$GM \geq Nb / (KW \tan(T)) \quad (\text{ft})$$

Where:

- N = number of passengers
- W = displacement of vessel in long tons.
- T = 14° or the angle of heel at which the deck edge is first submerged, whichever is less
- b = distance in feet from the centerline of the vessel to the geometric center of the passenger deck on one side of the centerline
- b = 2.5 feet
- K = 24 passengers/LT
- B = 12.4 feet
- D = 5.46 feet (freeboard depth)

EXECUTIVE SUMMARY

On October 2, 2005 the NY state certified vessel Ethan Allen was touring Lake George with 47 passengers and one NY State licensed crewmember on board. The vessel proceeded northbound and approached an area on the lake called Cramer Point when the master began a turn to starboard. According to most of the passengers, the vessel heeled to port and capsized. After remaining inverted on the surface for a short period, the vessel subsequently sank. The master and 27 passengers survived. Twenty passengers died.

At the request of NTSB, JMS has performed intact stability calculations for the passenger vessel ETHAN ALLEN. Results of the intact stability analysis, Tasks 1-5, are presented in Ref. 1. This report presents the results of Task 6 which evaluates the effect of partial intact flooding of the main engine and forward compartments. The actual passenger loading condition at the time of the accident is used as a baseline condition. The effect of transverse movement of the passenger loading is also analyzed.

Appendix A provides a general description of how curves of righting arm vs. angle of heel are developed and the significance of calculated righting energy vs. the various loading conditions. The Appendix also discusses the significance of righting energy in maintaining vessel stability to account for the variability in environmental conditions and other factors affecting stability.

VESSEL PARTICULARS

Owner	Shoreline Cruises, Lake George, NY
Built	1964, The Anchorage, Warren, RI
Model	Dyer 40
Hull No.	7
LOA	39.5 ft
LBP	33.5 ft
Beam	12.4 ft (molded, at MS)
Depth	5.93 ft (molded, at MS)

Table 1, VESSEL PARTICULARS

DESCRIPTION OF COMPUTER MODEL

A computer model of the vessel was created using Herbert Engineering Corporation's hydrostatic software package, HECSALV Version 7.6.6. This model includes hull offsets and hydrostatic properties, compartments and subdivision, and weights and centers. Hull offsets were obtained by laser measurement of the ETHAN ALLEN. Details of the HECSALV model are contained in Ref. 1.

ASSUMPTIONS

Unless otherwise noted, the following assumptions apply to this analysis.

1. The transverse bulkheads at the forward and aft ends of the engine room are considered watertight.
2. The flooded compartments are considered intact. Flooding is from an unspecified source.
3. Flooding is not considered to be constrained by the longitudinal stringers. This reflects either the existence of limber holes or water spilling from one side to the other as a result of vessel motion or heel. The source of the flooding is not a factor since the water will be free to settle in the lowest part of the compartment.
4. The vessel is operating in fresh water. All flood water is also fresh (62.4 lb/ft³).
5. The fuel tank is 75% full.
6. The free surface correction is calculated directly using the moment transference method.
7. The passenger VCG is approximately 2 feet above the main deck.

8. Heel to port and trim forward are negative by convention throughout this report.
9. The 2005 Wood Canopy lightship condition is used for this analysis. A summary of the vessel lightship condition is presented in Table 2.

Table 2, LIGHTSHIP CHARACTERISTICS

RESULTS

Passenger seating is arranged with 8 rows of bench seats. Each row has a three person bench on the port side and a two person bench on the starboard side. The aisle between them is slightly to starboard of centerline. Three additional 3-person benches are at the forward end of the vessel, symmetrical on the centerline. The vessel operator station is aft on the starboard side. This provides for a total of 49 passenger seats and one crew seat. At the time of the accident there were 47 passengers and one crew member on board. The total weight of passengers and crew was 8,522 lbs. Excluding the crew member, the average weight per passenger is 177.7 lbs. The actual passenger location and weight was provided by NTSB and is included in Appendix B. Figure 1 shows the actual passenger arrangement that is used for the flooding cases presented below. The results show that the total passenger (and crew) transverse center of gravity was 0.2 feet to port of centerline and the longitudinal center of gravity was 0.36 feet forward of midship. This created a 2.2 degree heel to port and 0.71 foot trim forward (see Figure 2, DEPARTURE LOAD CASE).

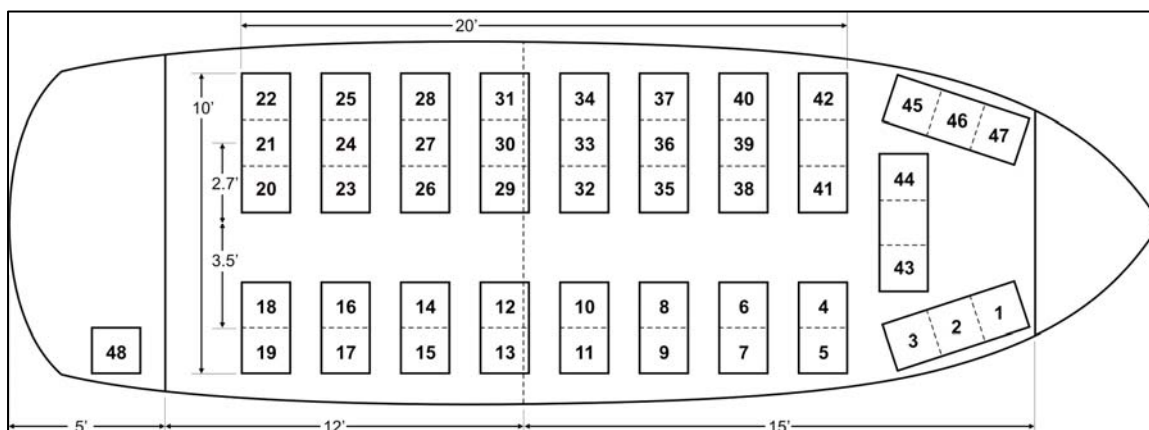

Figure 1, PASSENGER ARRANGEMENT

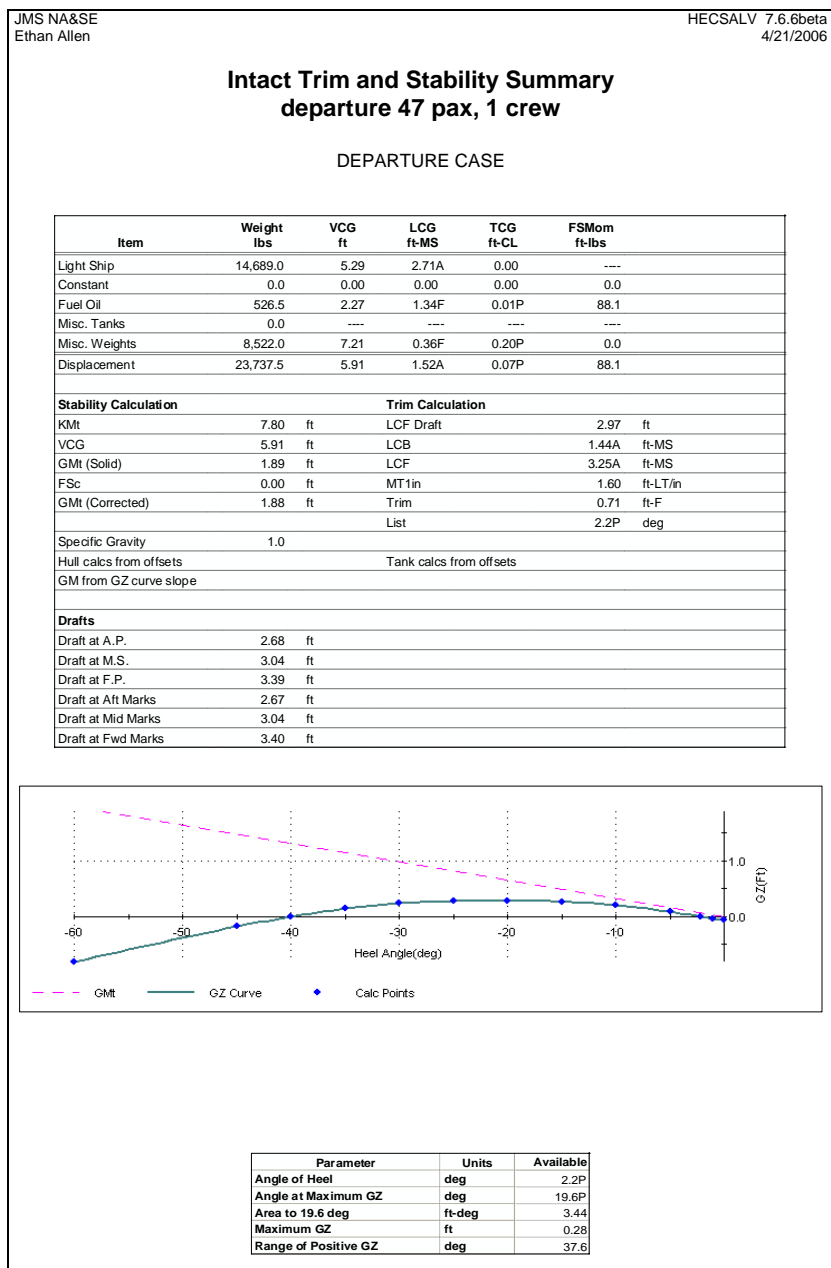

Figure 2, DEPARTURE LOAD CASE

Beginning with the passenger arrangement shown in Figure 1, JMS analyzed the effects on intact stability for progressive amounts of partial internal flooding of 1. the engine compartment and 2. the forward compartment taking into account obstructions such as the main engine and fuel tank. Metacentric height and the righting arm curve for each level of flooding are provided in Appendices C and D. A summary of the cases is provided in Tables 3 and 4. Flooding levels are expressed both in terms of depth of water in the flooded space as well as total volume of water in the space. The depth of the water is derived from the tank table innage which assumes an even heel/trim condition (see Appendix E). There are several factors influencing the vessel's stability characteristics. The flooding adds weight low in the vessel, improving its stability, however, the loose water creates a free surface effect reducing the righting arm and increasing the heel. The effect is more pronounced with flooding in the engine compartment where a larger heeling arm can be developed than in the narrower forward compartment.

Table 4, FORWARD COMPARTMENT FLOODING SUMMARY

The effect of transverse movement of the passenger load was also analyzed. A passenger (and crew) transverse center of gravity of 0, -0.2 feet, -0.4 feet, -0.6 feet, -0.8 feet, and -1.0 feet are compared (see Table 5). The transverse weight shift has no effect on metacentric height (GM) but it does increase heel and reduce the righting arm. In this case, the righting arm disappears with the passenger weight shifted 1.0 foot off centerline (or 0.8 feet from the initial loading condition). Detailed results are presented in Appendix E.

		TRANSVERSE CENTER OF PASSENGER WEIGHT FROM CENTERLINE

Table 5, TRANSVERSE CENTER OF PASSENGER WEIGHT

APPENDIX A

TRANSEVERSE STABILITY

EXCERPT FROM *MARINE CASUALTY RESPONSE: SALVAGE ENGINEERING*

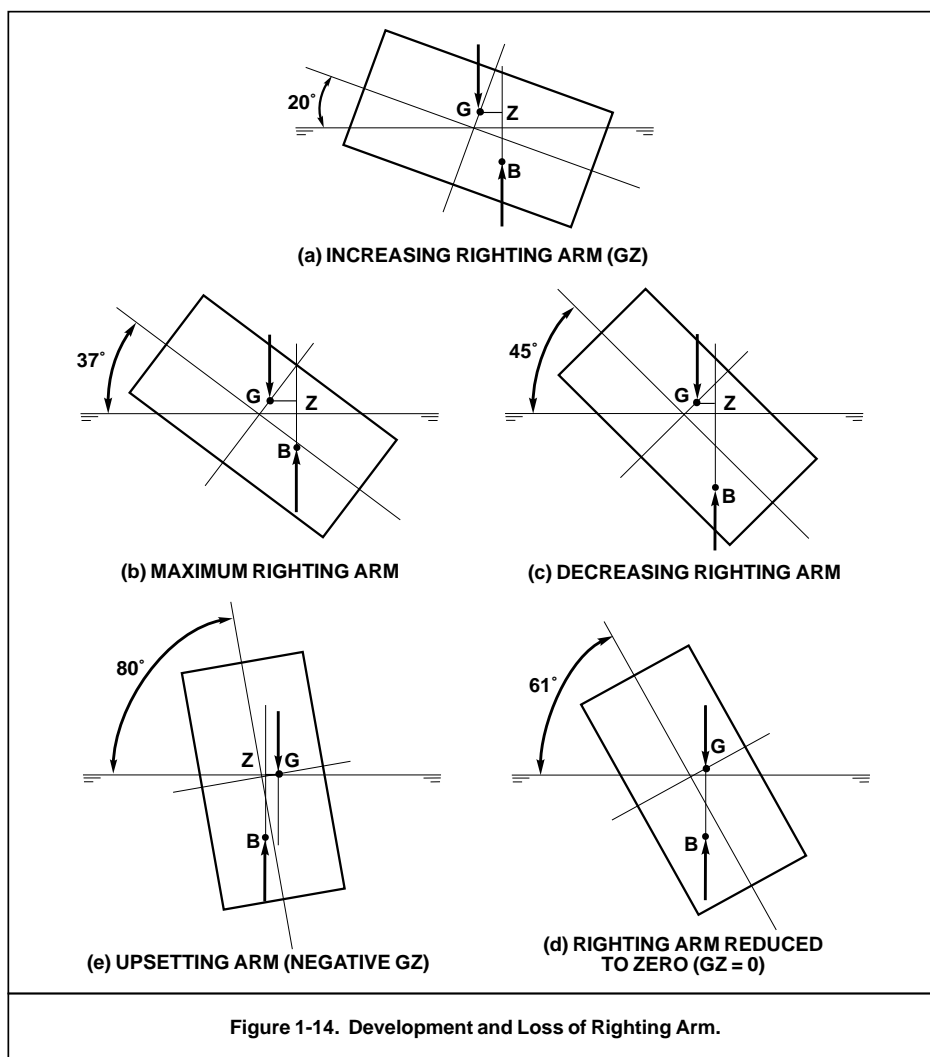

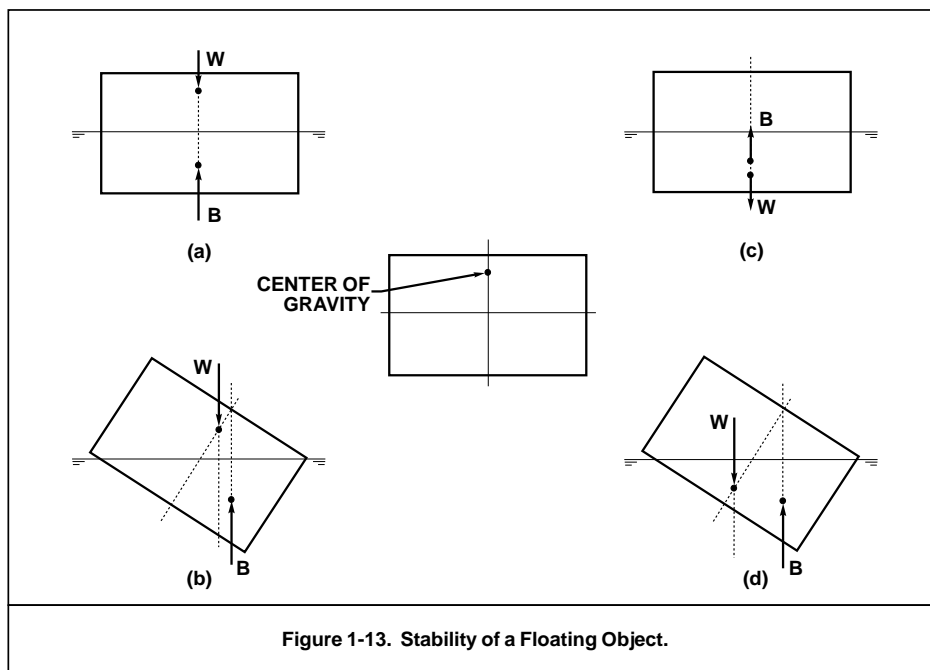

JMS NAVAL ARCHITECTS & SALVAGE ENGINEERS AND THE AMERICAN SOCIETY OF NAVAL
ENGINEERS, 1999

1-5 TRANSVERSE STABILITY

Transverse stability is the measure of a ship's ability to resist rotation about its longitudinal axis and return to an upright position after being disturbed by an upsetting force. The following paragraphs define the elements of transverse stability and provide methods to calculate the transverse stability characteristics of a vessel.

1-5.1 Equilibrium and Stability. A ship floating at rest, with or without list and trim, is in static equilibrium; that is, the forces of gravity and buoyancy are equal and acting in opposite directions in line with one another. Stability is the tendency of a ship to return to its original position when disturbed after the disturbing force is removed. Stability can be described as positive, negative, or neutral.

1-5.2 Internal Forces. The internal forces affecting floating bodies are the forces of gravity and buoyancy. Both of these forces act at all times on wholly or partially submerged bodies. Figure 1-13 illustrates the relationship between the forces of buoyancy and gravity. Assuming the prism floats with half its volume submerged, and with the center of gravity located as shown, the prism can come to rest in either position (a), with the center of gravity directly above the center of buoyancy, or (c), with the center of buoyancy above the center of gravity. In either position, the forces of buoyancy and gravity act along the same vertical line. If the prism is inclined from (a) to (b), or from (c) to (d), a couple, or righting moment, is developed between the lines of action of buoyancy and gravity that tends to move the body back to its original position, i.e., the body floats with positive stability in either position. In position (a), with the center of gravity above the center of buoyancy, stability is provided by the body's shape, or form, and is termed *form stability*. If the width of the prism is reduced while the center of gravity remains on the centerline at the same location, a situation arises in which the center of buoyancy does not move far enough to be to the right of the center of gravity as the body is inclined from (a) to (b). The body can then attain positive stability only in position (c), with the center of buoyancy above the center of gravity. Bodies floating with the center of buoyancy above the center of gravity develop positive initial righting moments regardless of shape. This mode of stability is called *weight stability*. Sailing yachts with deep weighted keels, spar buoys, conventional ships with very low centers of gravity, and submarines all exhibit weight stability. Capsized ships floating upside down very often have their centers of gravity below the center of buoyancy, and operate in a weight stability mode.

The center of buoyancy of a ship moves as the ship is inclined, in a manner that depends on the shape of the hull near the waterline. The center of buoyancy initially moves away from the centerline as the ship is inclined, as shown in Figure 1-14. At some angle of inclination, the center of buoyancy begins to move back towards a vertical reference line drawn through the original position of the center of buoyancy. The vertical line of action of the center of gravity continues to move outward as the ship is inclined. At some angle of inclination, the line of action of gravity moves outboard of the line of action of buoyancy, creating an upsetting moment. Ships that have slowly heeled through progressively greater angles of inclination will suddenly capsize when this angle of zero righting moment (angle of vanishing stability) is passed.

In Figure 1-15, the prism is assumed to be neutrally buoyant so that it is wholly submerged but clear of the bottom. An inclination from (a) produces an upsetting moment that tends to rotate the prism away from its initial position. Conversely, a inclination from (c) produces a righting moment. A submerged object clear of the bottom or other restraints can therefore have positive stability in only one position, that is, with the center of buoyancy above the center of gravity. Submerged objects therefore operate in a weight stability mode. The difference in behavior of floating and submerged objects is due to the fact that the center of buoyancy of a submerged object is fixed at the center of volume of the object, while the center of buoyancy of a floating object will generally shift when the object is inclined. Because the center of buoyancy of a submerged object is fixed, the righting moment cannot change to an upsetting moment as the object inclines unless the position of the center of gravity shifts. Stability of submarines and other submerged objects is discussed more completely in the *U.S. Navy Ship Salvage Manual, Volume 4* (S0300-A6-MAN-040).

Figure 1-16 shows how a stable ship subjected to normal disturbances will develop moments tending to return the ship to its original position. A couple is formed as the lines of action of the opposing forces of gravity and buoyancy are separated. The arm of this couple, called the *righting arm*, is the lever to which the ship's weight is applied to right the ship. Figure 1-17 shows the *upsetting arm* developed when unstable ships are disturbed.

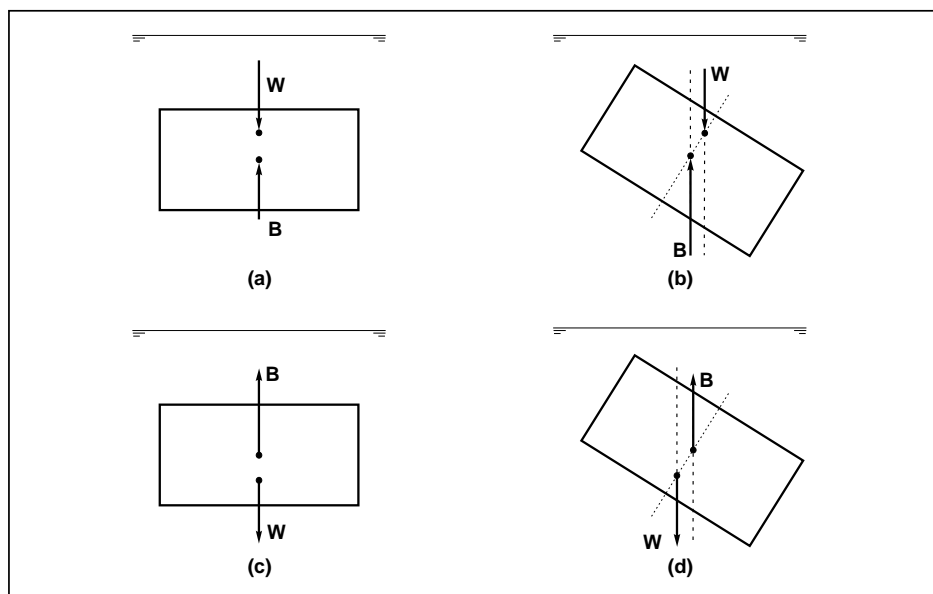

Figure 1-15. Stability of a Submerged Object.

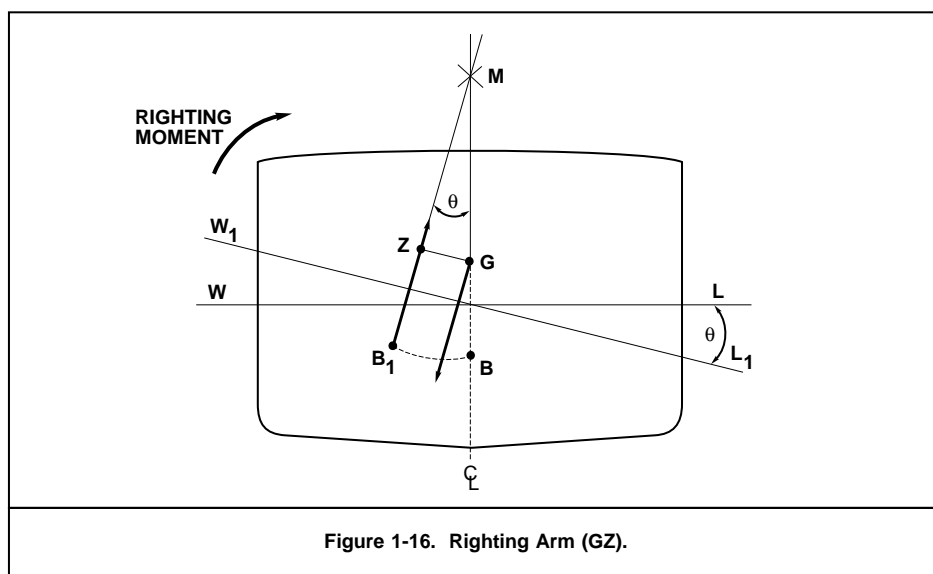

Figure 1-16. Righting Arm (GZ).

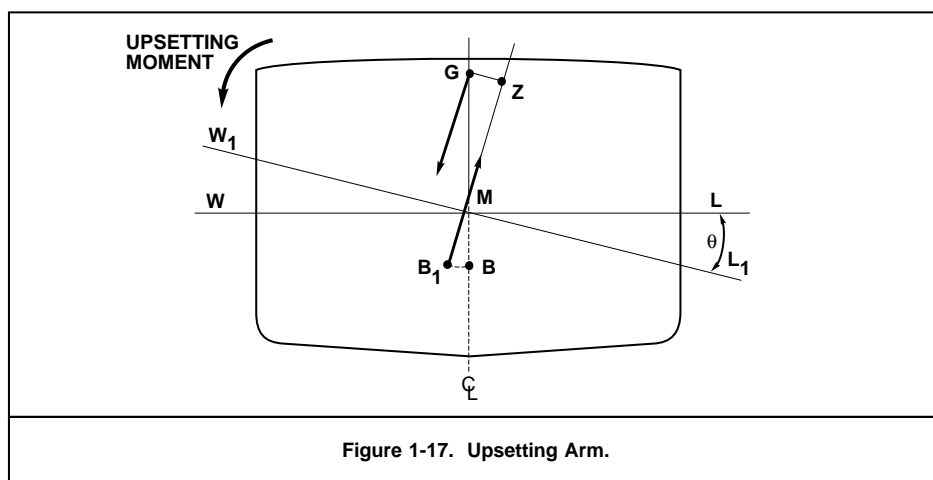

Figure 1-17. Upsetting Arm.

1-5.3 External Forces.

Ships are inclined by various external forces:

- Wave action,
- Wind,
- Collision,
- Grounding,
- Shifting of onboard weights, and
- Addition or removal of weight.

Any inclination of a ship can be termed *heel*, but inclinations are broadly defined as *heel*, *list*, or *roll* depending on the duration and nature of the forces causing the inclination.

- **Heel** – The term heel is specifically applied to noncyclic, transient inclinations caused by forces that may be removed or reversed quickly. Such forces include wind pressure, centrifugal force in high-speed turns, large movable weights, etc.
- **List** – A list is a permanent, or long-term inclination, caused by forces such as grounding or offcenter weight that are not likely to be removed suddenly.
- **Roll** – When an inclining force is suddenly removed, a ship does not simply return to its upright position, but inclines to the opposite side and oscillates, or rolls, about its equilibrium position for some time before coming to rest. The natural rolling period (period of roll assumed by a ship free of restraints and exciting forces) is a function of weight and buoyancy distribution. Rolling is cyclic in nature and is induced or aggravated by short duration, repetitive or cyclic forces, such as wave forces.

1-5.4 Heights of Centers. The relative heights of the centers of gravity and buoyancy and the metacenter govern the magnitude and sense of the moment arms developed as the ship inclines. They are, therefore, the primary indicators of a ship's initial stability. Nominally, the symbols *KG*, *KB*, and *KM* indicate the heights of the centers of gravity and buoyancy and the metacenter above the *bottom of the keel*, while the symbols *VCG* and *VCB* indicate the vertical positions of the centers of gravity and buoyancy, measured from the *baseline*. In practice, *KG/KB* and *VCG/VCB* are used almost interchangeably; in steel ships with flat plate keels, the difference in height above baseline and keel for any point is generally less than two inches and is not significant.

1-5.4.1 Height of the Center of Gravity. The height or vertical position of the center of gravity above the keel (*KG* or *VCG*) is defined by weight distribution. *KG* can be varied considerably without change of displacement by shifting weight up or down in the ship. Conversely, it is possible to add or remove weight without altering *KG*. In most ships, the center of gravity lies between six-tenths of the depth above the keel and the main deck:

$$0.6D < KG < D$$

where:

$$D = \text{hull depth, keel to main deck}$$

For barges with raked or ship-shaped bows and cut-up sterns, lightship *KG* can be estimated as 0.53D. For tank barges, *KG* for full load varies little from the lightship value.

Table 1-4 gives very approximate values for the height of the center of gravity for several types of merchant ships at *lightship*, and for some naval ship types at *full load*. Calculation of *KG* can be a laborious and time-consuming process, but ignorance of the height of a ship's center of gravity invites disaster. If the height of the ship's center of gravity is known for any condition of loading (lightship, for example), and the location of added or removed weights is known, the new height of the center of gravity can be calculated¹:

$$KG_{\text{new}} = \frac{W_{\text{old}} KG_{\text{old}} + \sum w(kg)}{W_{\text{old}} + \sum w}$$

where:

- KG* = height of the ship's center of gravity, *G*, above the keel
- W* = total weight of the ship and contents
- w* = individual weights added (+) or removed (-)
- kg* = height above keel of centers of gravity of added or removed weights, *w*

¹ Applied Naval Architecture, R. Munro-Smith, 1967	
² Jamestown Marine Services, 1990	

Height of the center of gravity of cargo can generally be obtained from the ship's officers, usually the chief mate. In the absence of better information, the design estimations proposed by R. Munro-Smith (*Applied Naval Architecture*, 1967) shown in Table 1-5 may be helpful.

1-5.4.2 Height of the Center of Buoyancy. The height of the center of buoyancy above the keel (KB) is solely a function of the shape of the underwater volume. As the centroid of the underwater hull, the center of buoyancy is lower in flat-bottomed, full-bodied ships, such as tankers and ore carriers, than in finer lined ships like destroyers or frigates. Disregarding changes in the shape of the immersed hull due to trim and heel, KB of any ship is a function of displacement, and therefore of draft. The height of the center of buoyancy can be calculated by summing incremental waterplane areas (a_{wp}) multiplied by their heights above the keel (z) and dividing the result by the displacement volume (∇):

$$KB = \frac{1}{\nabla} \int a_{wp} z \, dz$$

This expression can be evaluated by numerical integration methods if accurate drawings or offsets are available. In practice, KB can be approximated with sufficient accuracy for salvage work as $0.52T$ for full-bodied ships and $0.58T$ for fine-lined ships. At very light drafts, KB is closer to the given waterline because the lower waterlines are usually much finer than the waterlines in the normal draft range. As a vessel's underwater hull form approaches a rectangular prism ($C_B = 1.0$), KB approaches $0.5T$. The following empirical relationships give estimates for KB that are very close to calculated values for merchant vessels of ordinary form at normal drafts:

$$KB = \frac{1}{3} \left(\frac{5T}{2} - \frac{\nabla}{A_{wp}} \right) \quad (\text{Morrish's Formula})$$

$$KB = T_m \frac{A_{wp}}{A_{wp} + \frac{\nabla}{T_m}} \quad (\text{Posdunine's Formula})$$

where:

$$\begin{aligned} T_m &= \text{mean draft, [length]} \\ \nabla &= \text{displacement volume, [length}^3\text{]} \\ A_{wp} &= \text{waterplane area, [length}^2\text{]} \end{aligned}$$

1-5.4.3 Metacentric Height. The *transverse metacentric height* (GM_T), commonly called the *metacentric height*, of a ship is the vertical separation of the center of gravity and the transverse metacenter (see Figure 1-4) and is a primary indicator of initial stability. A ship with a positive metacentric height (G below M) will tend to right itself by developing righting arms as soon as an inclining force is applied. A ship with a negative metacentric height (G above M) will list to either port or starboard with equal facility until the centers of buoyancy and gravity are on the same vertical line, and thereafter develop positive righting arms. This condition, known as *lolling*, is a serious symptom of impaired initial stability. Metacentric height is calculated by subtracting the height of the center of gravity from the height of the metacenter above the keel:

$$GM_T = KM_T - KG$$

Transverse Metacentric Radius. The transverse metacentric radius (BM_T) is the vertical distance between the center of buoyancy and the metacenter. This distance is termed a radius because for small heel angles, the locus of successive centers of buoyancy approximates a circular arc, with the transverse metacenter as its center. Metacentric radius is equal to the moment of inertia of the waterplane about its longitudinal centerline (*transverse moment of inertia*, I_T) divided by the underwater volume of the hull (∇):

$$BM_T = \frac{I_T}{\nabla}$$

Table 1-5. Approximate KG of Cargo in Full Holds.

Hold/Space	KG of Cargo (D = depth of hold)
No. 1	$0.7D + \text{depth of double bottom}$
No. 2	$0.7D + \text{depth of double bottom}$
No. 3	$0.7D + \text{depth of double bottom}$
No. 4	$0.7D + \text{depth of double bottom}$
No. 5	$0.7D + \text{depth of double bottom}$
'tween decks	height above keel to half depth of 'tween deck at mid length of the space

Based on full holds (homogeneous cargo) in general cargo ship with machinery amidships, three holds forward and two aft. In ships with extensive parallel midbody, it may be more appropriate to apply the expression for hold No. 3 to all holds in the parallel midbody, with the expression for No. 1 or No. 2 (depending on fineness of forebody) applied to the forward most hold. A similar analysis should be applied to holds aft of the machinery space, if any.

For a rectangular waterplane, $I_T = LB^3/12$, $\nabla = LBT$ and:

$$\begin{aligned} BM_T &= \frac{I_T}{\nabla} = \frac{\frac{LB^3}{12}}{LBT} \\ &= \frac{B^2}{12T} \end{aligned}$$

where:

- L = length between perpendiculars, [length]
- B = beam, [length]
- T = mean draft, [length]

If the waterplane shape can be accurately defined, the moment of inertia can be determined by numerical integration. If not, the transverse moment of inertia of most ships' waterplanes can be approximated by:

$$I_T \approx C_{IT} LB^3$$

where C_{IT} is the transverse inertia coefficient and is approximated by $C_{WP}^2/11.7$ or $0.125C_{WP} - 0.045$. These expressions for transverse inertia coefficient are derived from the analysis of numerous ships, and are reasonable approximations for use in salvage for ships with $C_{WP} < 0.9$. For ships with $C_{WP} > 0.9$, $LB^3/12$ is a closer approximation of the transverse moment of inertia of the waterplane.

Height of the Metacenter. The height of the metacenter above the keel is calculated by adding the metacentric radius to the height of the center of buoyancy above the keel:

$$KM = KB + BM$$

$$\therefore GM = KB + BM - KG$$

When denoting transverse metacenter, BM , KM , and GM , the subscript "T" is often omitted as understood.

Ships with large GM develop large initial righting arms and therefore respond to moderate disturbing forces with sharp, short-period rolling. These ships are said to be *stiff*. Ships with smaller metacentric heights develop smaller initial righting arms and roll more gently in a seaway. Ships with small metacentric heights are said to be *tender*. Insufficient initial stability results in constant rolling in even gentle seas, making work difficult, and may allow extreme rolling in heavier seas, perhaps causing the ship to take on water or capsize. Excessive initial stability, or stiffness, is also undesirable because it produces an uncomfortable ride, reduces personnel effectiveness, increases requirements on weapons stabilization systems, increases lateral acceleration loads on topside cargo and equipment, and increases hull stresses. These matters usually do not concern the salvage engineer, but very stiff rolling of a casualty under tow may damage sensitive equipment, loosen patches, or place excessive loads on damaged structure. The term *seakindly* is used to describe a ship whose metacentric height is great enough to give adequate stability, but not large enough to cause excessive stiffness.

The natural rolling period is a function of weight and buoyancy distribution and can be expressed as a function of GM and transverse radius of gyration (k):

$$T_R = \frac{2\pi k}{\sqrt{gGM}}$$

where:

- T_R = natural rolling period, seconds
- k = transverse radius of gyration of the ship mass, [length]
- = 0.4 to 0.5 times the beam, depending on depth and transverse weight distribution
- GM = transverse metacentric height, [length]
- g = acceleration due to gravity, [length/sec²]

If GM and k are expressed in feet, and g is taken as 32.174 ft/sec^2 , the rolling period formula reduces to:

$$T_R = \frac{1.108k}{\sqrt{GM}}$$

and:

$$GM = \left(1.108 \frac{k}{T_R} \right)^2$$

If the natural rolling period is known, GM can be estimated. Taking radius of gyration k as beam (B) multiplied by a coefficient (C), a conservative estimate of GM can be made:

$$GM \approx \left(\frac{CB}{T_R} \right)^2$$

The coefficient C can be taken as 0.4 to 0.5 for naval surface ships (0.44 average), 0.4 to 0.45 for submarine hulls based on bodies of revolution, and 0.32 to 0.37 for other submarines. *Ships and Marine Engines, Volume IV, The Design of Merchant Ships* (Schokker et al, 1953) gives some experimentally derived values for commercial vessels: 0.425 for large cargo and passenger liners, 0.385 for smaller passenger liners, 0.390 for a loaded passenger liner, and 0.405 for an ore ship in ballast. This same text references Laursen's possibly more correct approach of expressing radius of gyration as a function of both beam and depth:

$$k = C\sqrt{B^2 + D^2}$$

where the constant C ranges from 0.35 to 0.39 for cargo ships of ordinary form.

The rolling period formula will not give an accurate estimate of GM for a ship rolling in a seaway because the rolling period is modified by wave and wind forces. Significant changes in GM will be reflected by marked changes in rolling period; increased rolling period is a sign of deteriorating stability. An empirically derived relationship holds that stability is adequate when:

$$T_R \leq 2\sqrt{B}$$

where:

B = beam, ft

1-5.5 Righting Arm. At equilibrium, the forces of gravity and buoyancy act equally in opposition along the vertical centerline. As the center of buoyancy shifts with a heel, the two opposing forces act along separate and parallel lines. The forces establish the couple which tends to return a stable ship to the upright position. The distance GZ between the lines of action of the center of gravity and the center of buoyancy, as shown in Figure 1-16, is the righting arm. The sine of the angle of inclination (θ) is the ratio of GZ to GM .

$$\sin\theta = \frac{GZ}{GM}$$

$$\therefore GZ = GM \sin\theta$$

This relationship applies for heel angles so small that the waterplane shape is not appreciably changed, usually taken as less than 10 degrees for wall-sided ships and 7 degrees for fine-lined ships. At greater angles of heel, the metacenter moves away from the centerline and the relationship between GZ and GM no longer applies.

1-5.6 Righting Moment. The force applied to a righting arm (GZ) is the ship's weight. The righting moment (RM) developed at any angle of heel is given by:

$$RM = W \times GZ$$

At any angle of heel, the stability of the ship is measured by the righting moment developed. Since the righting moment is equal to the righting arm times displacement and displacement normally remains constant as the ship heels, the righting arm may also be used to measure stability for a given condition of loading. This assumption lends itself to the use of the cross curves of stability as discussed in Paragraph 1-5.9.

1-5.7 Change of Displacement. Any change of displacement will affect the righting moments developed by the ship. An increased displacement increases W in the expression $RM = W \times GZ$, but also affects GZ by:

- Increasing draft and thereby KB .
- Increasing ∇ , thereby reducing BM as I will not change significantly ($BM = I/\nabla$).

The height of the metacenter is normally reduced as displacement increases because the increase in KB is usually less than the reduction in BM . The opposite effects will be noted when displacement is decreased. Additionally, the location of the added weight will affect the location of the center of gravity and therefore GM and GZ . These effects are simultaneous but not normally compensatory. The net effect of a change in displacement may be either an increase or a decrease in righting moments. In general, the addition of low weight or removal of high weight will increase stability, but each change of displacement must be carefully analyzed to determine its exact effect.

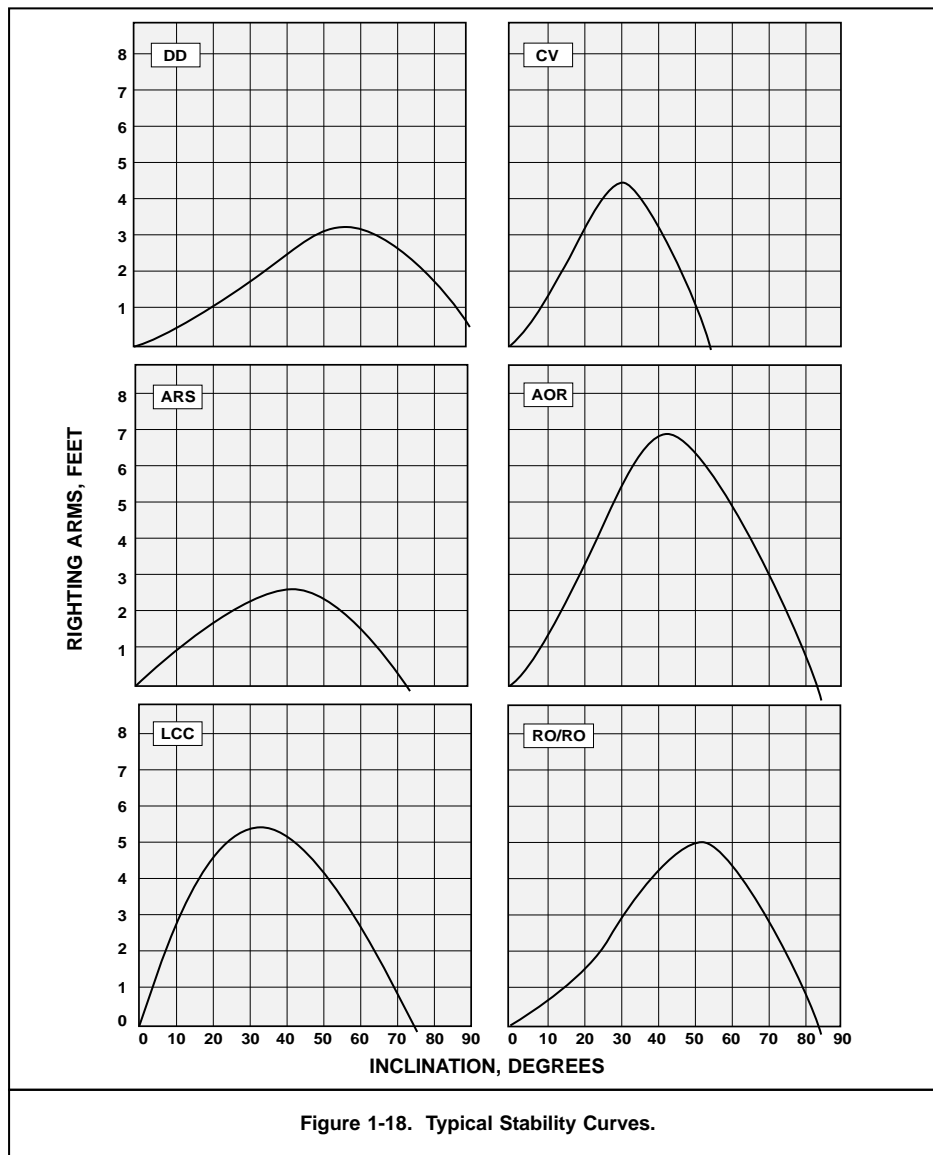

1-5.8 List. List, a long-term inclination of the ship to one side or the other, is caused by:

- Offcenter weight.
- Negative GM .
- A combination of offcenter weight and negative GM .

Before attempting to correct a list on a ship, the cause must be determined. Inappropriate corrective measures will only aggravate the situation.

A list caused by offcenter weight is identified by the ship's tendency to return to its listing condition when an external force is applied temporarily and then removed. A list caused by negative GM is identified by the ship's tendency to loll, or list to either side with equal facility, when disturbed. A list caused by a combination of offcenter weight and negative GM is identified by the ship's tendency to list with equal facility to either side, but with a greater degree of list to one side. Negative GM is the most serious condition that causes a list and should be corrected first. Paragraph 1-9.4 discusses the effects of negative GM in greater detail.

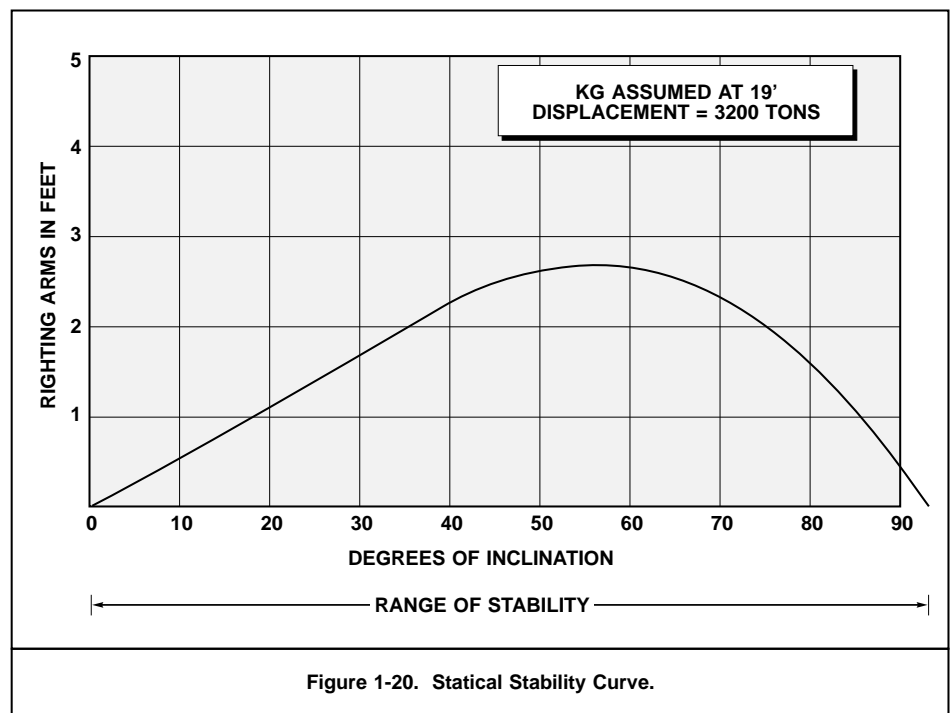

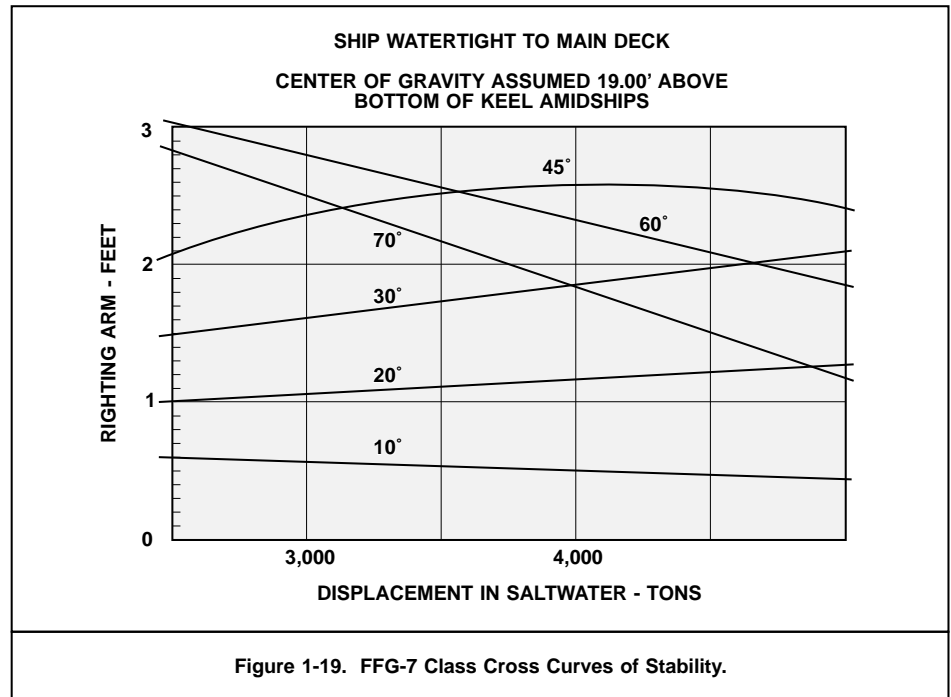

1-5.9 The Stability Curve. The righting arm GZ is the distance between the lines of action of buoyancy and gravity at any angle of heel. Since the expression $GZ = GM \sin\theta$ cannot be used at larger angles of heel, the righting arm for a given heel angle is determined by accurately locating the centers of gravity and buoyancy, and measuring the separation between their lines of action. If movable weights within the ship can be neglected, the center of gravity can be assumed to be fixed. As the ship heels, the center of buoyancy will move to the new center of the underwater volume, which can be determined by numerical integration or graphical means. As a ship heels, it also changes its trim to some extent to maintain constant displacement. This small change in trim can usually be disregarded when calculating righting arms. Centers of buoyancy for various inclinations, and the resulting righting arms are determined by numerical integration. These computations can be shortened somewhat by the methods described in Paragraph 1-5.11. A plot of righting arm against heel angle is variously called a *curve of statical stability*, *stability curve*, *righting arm curve*, or *GZ curve*. Figure 1-18 shows typical stability curves for various ship types.

1-5.9.1 Cross Curves of Stability. As a ship's displacement is variable, the designers prepare stability curves for a range of displacements. It is customary to plot righting arm values against displacement for each of a number of angles of inclination to create a group of curves known as *cross curves of stability*. By entering the cross curves with the displacement of the ship and reading the righting arms for each angle of heel, a stability curve for any displacement can be developed. Since height of the center of gravity varies with loading, an assumed position of the center of gravity was used by the designer to develop the cross curves of stability. Once the stability curve has been corrected for the true location of the center of gravity, the following stability data can be obtained:

- Range of stability.
- Righting arm and moment at any angle of inclination.
- Maximum righting arm and moment.
- Angle of the maximum righting arm and moment.
- Metacentric height.
- Angle of deck edge immersion.

The following examples use the FFG-7 Class cross curves of stability from Figure 1-19 to develop the initial and corrected stability curves. Figure 1-20 is the stability curve as taken from the cross curves for a displacement of 3,200 tons.

1-5.9.2 Correction for Actual KG . If the actual center of gravity lies above the assumed center of gravity, the metacentric height is decreased and the ship is less stable; conversely, if the actual center of gravity is below the assumed center, the metacentric height is increased and the ship is more stable.

Figure 1-21 shows that the actual righting arm, G_1Z_1 , is equal to the assumed righting arm plus or minus the vertical distance between the actual and assumed KG , multiplied by the sine of the angle of heel:

$$G_1Z_1 = GZ \pm GG_1 \sin \theta$$

The actual, or corrected, stability curve can be constructed graphically as a sine curve correction.

The $GG_1 \sin \theta$ curve is plotted to the same scale as the curve of statical stability as shown in Figure 1-22. The ordinates of the corrected curve are the differences between the ordinates of the two curves and can be picked off and plotted using dividers, as shown, or determined by tabular calculation.

If the actual height of the center of gravity is less than the assumed height, the correction curve is plotted below the horizontal axis.

The assumed KG is sometimes called *pole height*. It is a common practice, especially with European designers, to develop cross curves based on an assumed pole height of zero. Since the assumed position of the center of gravity coincides with the keel, the resulting cross curves are termed KN curves.

1-5.9.3 Range of Stability. The range of stability—the range of inclinations through which the ship develops positive righting arms—is indicated by the intersections of the stability curve with the horizontal axis. For the corrected stability curve in Figure 1-22, the range of stability is from 0 to 75 degrees.

$$G_1 Z_1 = GZ - GG_1 \sin \theta$$

$$G_2 Z_2 = GZ + GG_2 \sin \theta$$

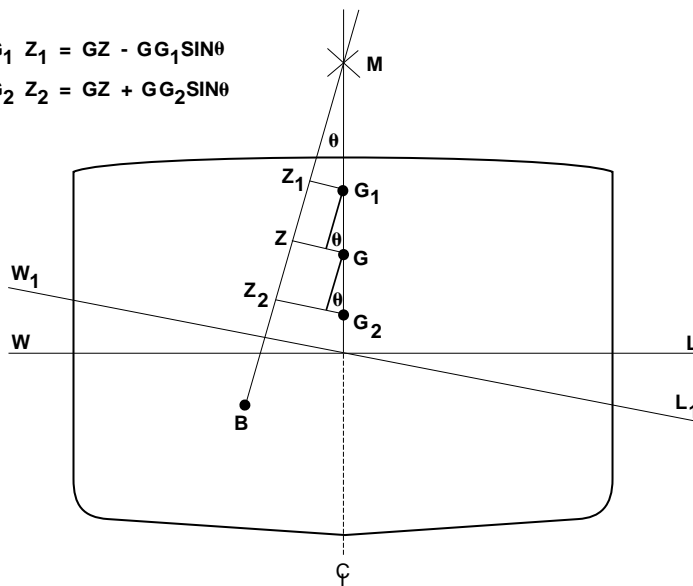

Figure 1-21. Assumed KG for Stability Curve.

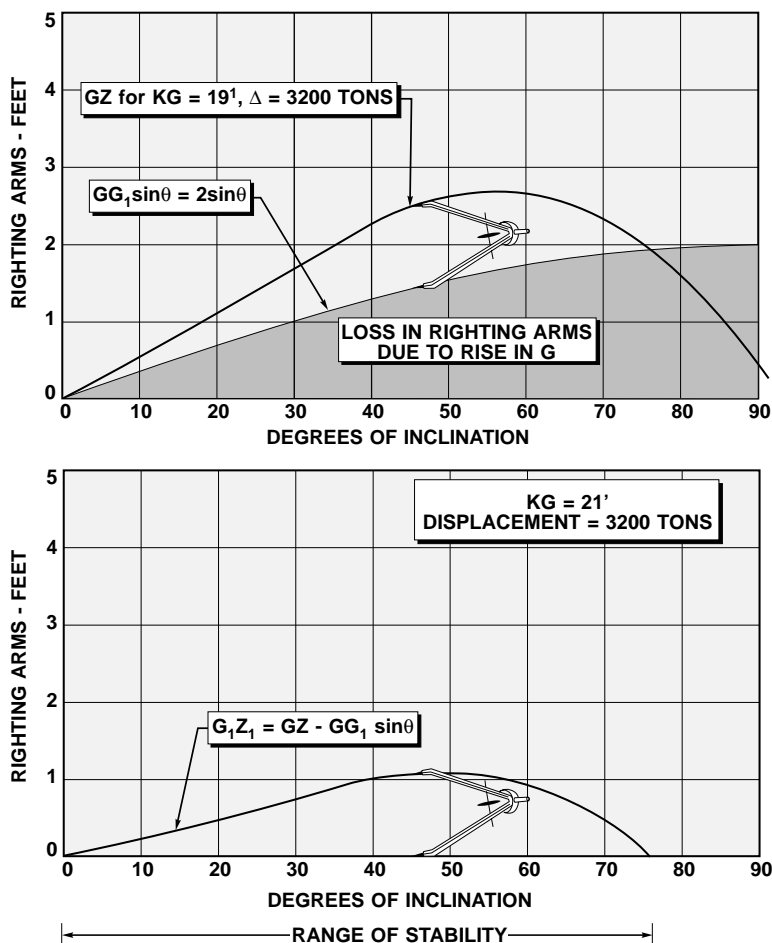

Figure 1-22. Correction to Stability Curve, G Two Feet Higher Than Assumed.

1-5.9.4 Righting Arm and Righting Moment. The righting arm at any inclination is read directly from the curve. Because each stability curve applies only to a specific displacement and KG , the righting moment can be obtained directly for any angle by multiplying the righting arm by the displacement. Maximum righting arm, maximum righting moment, and angle of maximum righting moment can be determined by inspection of the stability curve. From the corrected stability curve in Figure 1-22, maximum righting arm is approximately 1.1 feet at 51 degrees of inclination, giving a maximum righting moment of 3,520 foot-tons ($1.1 \text{ ft} \times 3,200 \text{ tons}$). Maximum righting arm and the angle at which it occurs are important parameters when an upsetting moment is applied gradually or statically. Once the upsetting moment exceeds the maximum righting moment, the ship will list past the angle of maximum righting arm. If the upsetting moment is not immediately removed, the ship will capsize, because as the ship heels to progressively greater angles, righting moment, already less than the upsetting moment, will steadily decrease. However, ships can, and do, safely roll past their angle of maximum righting arm in response to short-term or cyclic upsetting forces.

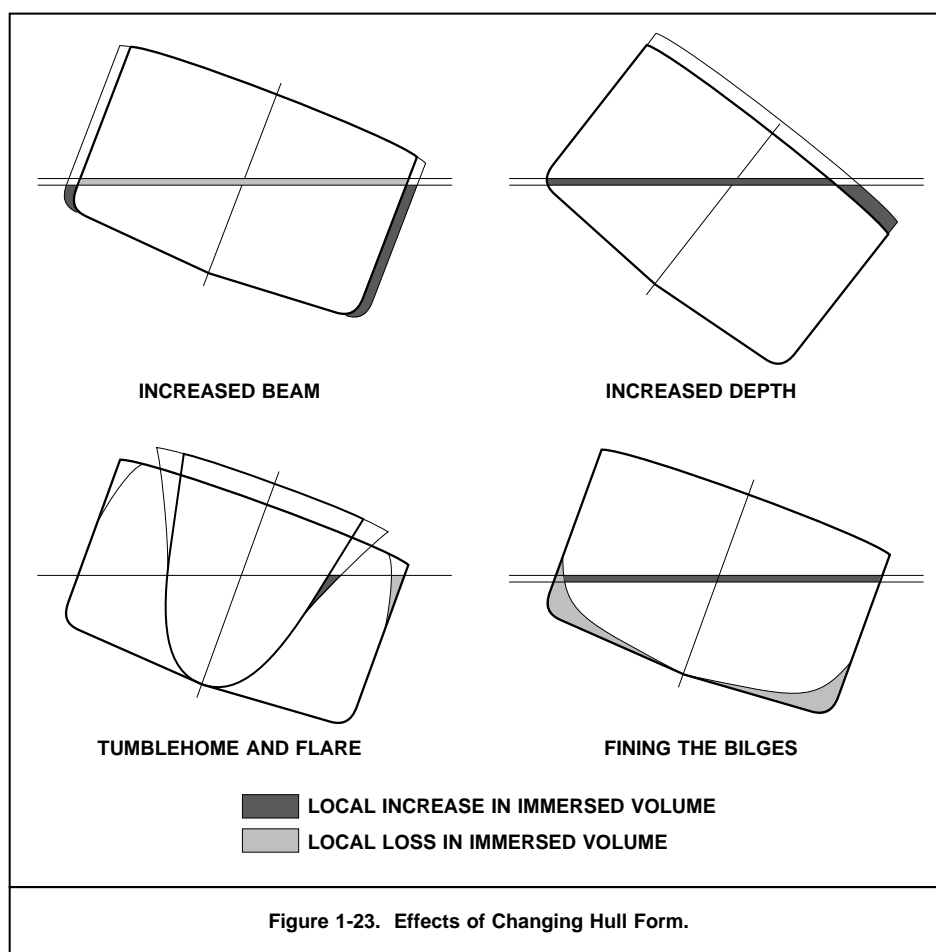

1-5.9.5 Metacentric Height. GM is the measure of the slope of the GZ curve at the origin. The metacentric height is equal to the height of the intersection of a tangent to the statical stability curve at the origin with a perpendicular to the horizontal axis at 57.3 degrees (one radian). Although metacentric height can be approximated from a stability curve by this means, it is more common that GM is known and the intercept is sketched to help draw the initial part of the stability curve. The corrected stability curve in Figure 1-22 indicates a GM of approximately 1.2 feet.

1-5.9.6 Angle of Deck Edge Immersion. For most hull forms, an inflection point in the curve corresponds roughly to the angle of deck edge immersion. This point is not necessarily at or near the angle of maximum righting arm. The inflection results from the abrupt change in the shapes of the waterplane and underwater volume as the deck edge is immersed. The rate of increase in righting arm has changed from positive to negative—i.e., righting arms are still increasing, but at a slower rate. The angle of deck edge immersion varies along the length of the ship, but lies within a relatively narrow range for the large midbody sections that have the greatest influence on the stability curve. The stability curve in Figure 1-22 shows the angle of deck edge immersion to be about 38 degrees.

1-5.9.7 Righting Energy. The area under the stability curve, (foot-degrees, meter-radians), is a measure of the ship's dynamic stability—its ability to absorb energy imparted by winds, waves or other external forces. A ship with very little area (righting energy) under its stability curve could be rolled past its range of stability and capsized by even a momentary disturbance.

1-5.10 Effects of Hull Form on the Stability Curve. While initial stability (righting arms at small angles of heel) depends almost entirely on metacentric height, the overall shape of the stability curve is governed by hull form. Figure 1-23 shows how changing hull form increases or decreases righting arm by altering the position and movement of the center of buoyancy. Figure 1-24 (Page 1-40) illustrates how altering hull form affects the stability curve as described in the following paragraphs.

1-5.10.1 Beam. Of all the hull dimensions that can be varied by the designer, beam has the greatest influence on transverse stability. Metacentric radius (BM) was shown to be proportional to the ratio B^2/T in Paragraph 1-5.4.3. BM , and therefore KM , will increase if beam is increased while draft is held constant. If freeboard is held constant while beam is increased, the angle of deck edge immersion is decreased; righting arms at larger angles and the range of stability are reduced. If the depth remains constant, overall stability will be reduced because KB decreases, increasing BG , although this will be offset at small angles by the increase in BM .

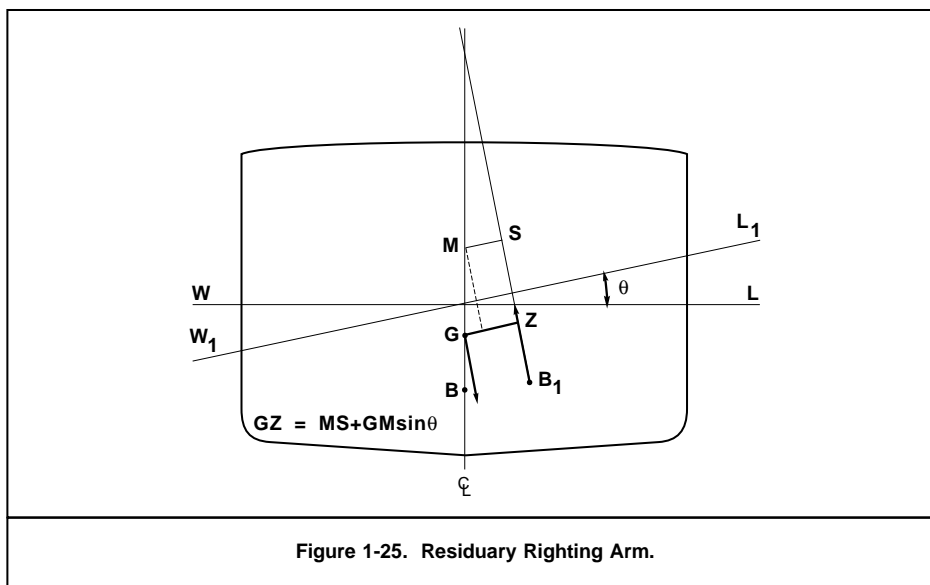

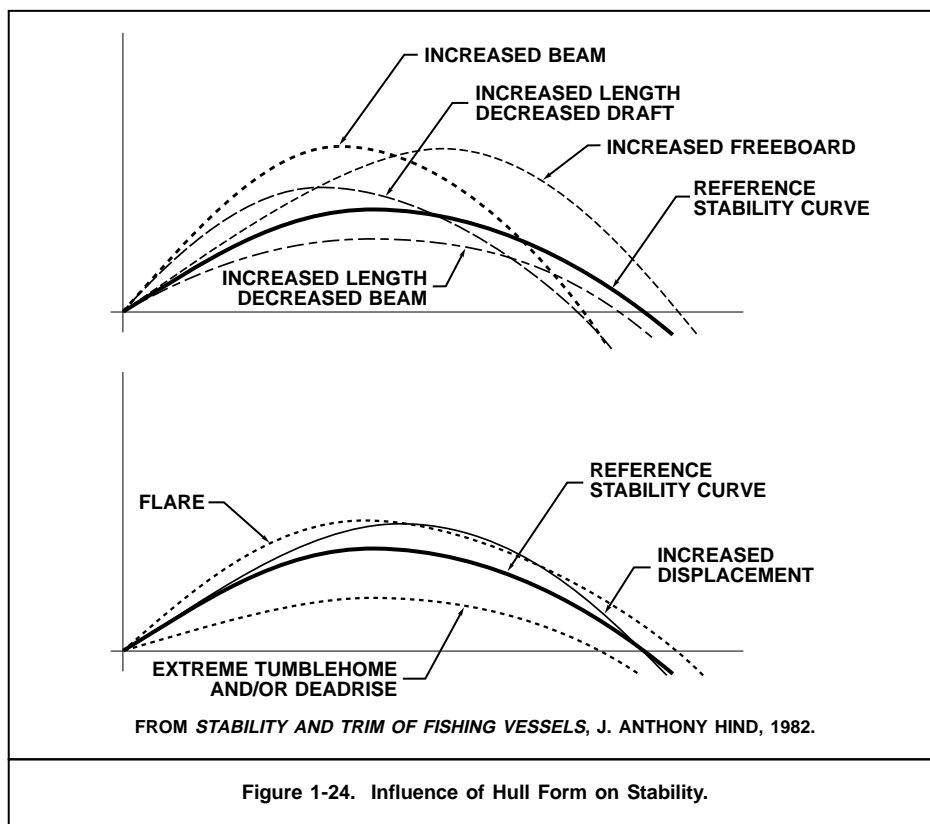

1-5.10.2 Length. If length is increased proportionally to displacement, with beam and draft held constant, KB and BM are unchanged. In practice, increasing length usually causes an increase in KG , reducing initial stability. If length is increased at the expense of beam, righting arms are reduced over the full range of stability. If length is increased at the expense of draft, righting arms will be increased at small angles, but decreased at large angles.

1-5.10.3 Freeboard. Increasing freeboard increases the angle of deck edge immersion, increasing righting arms at larger angles and extending the range of stability. If draft is held constant, increasing freeboard causes a rise in the center of gravity, mitigating the benefits of increased freeboard to some extent.

1-5.10.4 Draft. Reduced draft proportional to reduced displacement increases initial righting arms and the angle of deck edge immersion but decreases righting arms at large angles.

1-5.10.5 Displacement. If length, beam, and draft are held constant, displacement can be increased only by making the ship fuller. The filling out of the waterline will usually compensate for the increased volume of displacement, and BM , as a function of I/V , will increase. Height of the center of gravity will also be decreased by filling out the ship's form below the waterline. These changes will enhance stability at all angles.

1-5.10.6 Side and Bottom Profile. As can be seen in Figures 1-13 and 1-25, the increase in waterplane breadth and area caused by inclining a wall-sided ship can be calculated by simple geometry. The stability curve develops good early righting arms and range of stability. Extreme dead-rise (fining the bilges) or tumblehome in the vicinity of the inclined waterline reduces the increase in waterplane area and outward shift of the center of buoyancy, resulting in a shallow stability curve. Ships with flaring sides develop large righting arms because of the rapid increase in waterplane area and large shift of the center of buoyancy as the ship is inclined. A round-bottomed ship with vertical sides beginning somewhat above the water line, such as a tug or icebreaker, will roll easily to small angles of inclination but develop strong righting moments at large angles. In the same way, flare or watertight sponsons some distance above the water line will have no effect on initial stability, but will cause a sharp upward turn in the stability curve at larger angles of heel.

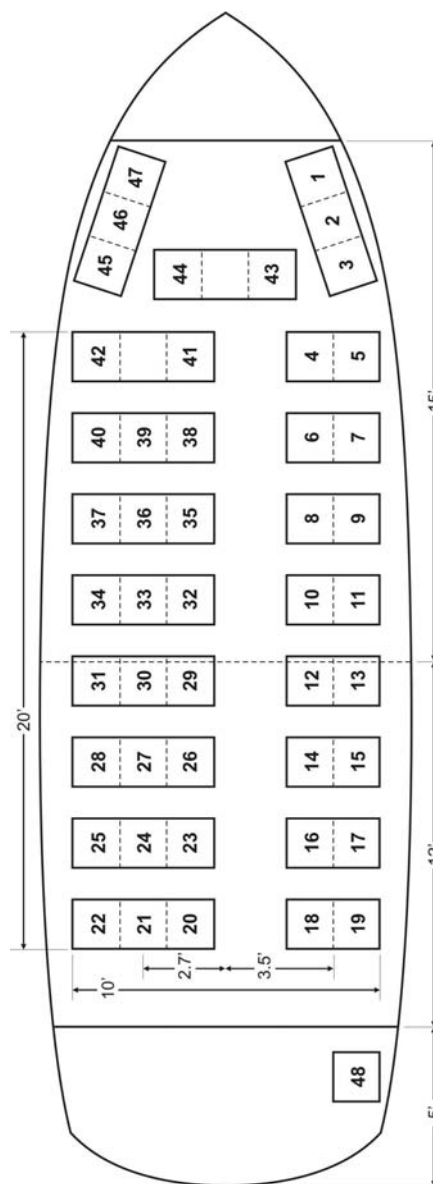

APPENDIX B

PASSENGER WEIGHT AND CENTERS

ETHAN ALLEN PASSENGER LOADING:

Seat	Weight lbs	LCG ft from AP	TCG ft from CL (port negative)
1	189	29.46	1.25
